Evaluating a process with structure function

Configure structure functions (single-channel) in a process object, create an instance, compute kinematics and evaluate.

Note the order of operations when setting up structure functions and phase space. The beams are first, they determine the `sqrts` value. We can also set up the chain of structure functions. We then configure the phase space. From this, we can obtain information about special configurations (resonances, etc.), which we need for allocating the possible structure-function channels (parameterizations and mappings). Finally, we match phase-space channels onto structure-function channels.

In the current example, this matching is trivial; we only have one structure-function channel.

⟨*Processes: execute tests*⟩+≡
```
    call test (processes_8, "processes_8", &
        "process evaluation with structure functions", &
        u, results)
```

Complete events

For the purpose of simplifying further tests, we implement a convenience routine that initializes a process and prepares a single event. This is a wrapup of the test `processes_10`.

⟨*Processes: public*⟩+≡
```
    public :: prepare_test_process
```

⟨*Processes: procedures*⟩+≡
```
    subroutine prepare_test_process (process, process_instance, model_list)
      type(process_t), intent(out), target :: process
      type(process_instance_t), intent(out), target :: process_instance
      type(model_list_t), intent(inout) :: model_list
      type(process_library_t), target :: lib
      type(string_t) :: libname
```

```
      type(string_t) :: procname
      type(string_t) :: run_id
      type(os_data_t) :: os_data
      type(qcd_t) :: qcd
      class(rng_factory_t), allocatable :: rng_factory
      class(prc_core_t), allocatable :: core_template
      class(mci_t), allocatable :: mci_template
      class(phs_config_t), allocatable :: phs_config_template
      real(default) :: sqrts
      libname = "processes_test"
      procname = libname
      run_id = "run_test"
      call os_data_init (os_data)
      allocate (rng_test_factory_t :: rng_factory)
      call prc_test_create_library (libname, lib)
      call reset_interaction_counter ()
      call process%init &
           (procname, run_id, lib, os_data, qcd, rng_factory, model_list)
      allocate (test_t :: core_template)
      allocate (mci_test_t :: mci_template)
      select type (mci_template)
      type is (mci_test_t);  call mci_template%set_divisions (100)
      end select
      allocate (phs_test_config_t :: phs_config_template)
      call process%init_component &
           (1, core_template, mci_template, phs_config_template)
      sqrts = 1000
      call process%setup_beams_sqrts (sqrts)
      call process%configure_phs ()
      call process%setup_mci ()
      call process%setup_terms ()
      call process_instance%init (process)
      select type (mci => process%mci_entry(1)%mci)
      type is (mci_test_t)
         ! This ensures that the next 'random' numbers are 0.3, 0.5, 0.7
         call mci%rng%init (3)
         ! Include the constant PHS factor in the stored maximum of the integrand
         call mci%set_max_factor (conv * twopi4 &
              / (2 * sqrt (lambda (sqrts **2, 125._default**2, 125._default**2))))
      end select
    end subroutine prepare_test_process
```

Here we do the cleanup of the process and process instance emitted by the previous routine.

⟨*Processes: public*⟩+≡
```
    public :: cleanup_test_process
```

⟨*Processes: procedures*⟩+≡
```
    subroutine cleanup_test_process (process, process_instance)

```

15.6 Process Stacks

For storing and handling multiple processes, we define process stacks. These are ordinary stacks where new process entries are pushed onto the top. We allow for multiple entries with identical process ID, but distinct run ID.

The implementation is essentially identical to the `prclib_stacks` module above. Unfortunately, Fortran supports no generic programming, so we do not make use of this fact.

When searching for a specific process ID, we will get (a pointer to) the top-most process entry with that ID on the stack, which was entered last. Usually, this is the best version of the process (in terms of integral, etc.) Thus the stack terminology makes sense.

⟨`process_stacks.f90`⟩≡
  ⟨*File header*⟩

  ```
  module process_stacks
  ```

  ⟨*Use strings*⟩
  ⟨*Use file utils*⟩
  ```
    use diagnostics !NODEP!
    use unit_tests
    use os_interface
    use sm_qcd
    use variables
    use models
    use rng_base

    use process_libraries
    use prc_test
    use processes
  ```

  ⟨*Standard module head*⟩

  ⟨*Process stacks: public*⟩

  ⟨*Process stacks: types*⟩

  ```
  contains
  ```

  ⟨*Process stacks: procedures*⟩

  ⟨*Process stacks: tests*⟩

  ```
  end module process_stacks
  ```

15.6.1 The process entry type

A process entry is a process object, augmented by a pointer to the next entry. We do not need specific methods, all relevant methods are inherited.

On higher level, processes should be prepared as process entry objects.

⟨Process stacks: public⟩≡
```
    public :: process_entry_t
```

⟨Process stacks: types⟩≡
```
    type, extends (process_t) :: process_entry_t
       type(process_entry_t), pointer :: next => null ()
    end type process_entry_t
```

15.6.2   The process stack type

For easy conversion and lookup it is useful to store the filling number in the object. The content is stored as a linked list.

The `var_list` component stores process-specific results, so they can be retrieved as (pseudo) variables.

⟨Process stacks: public⟩+≡
```
    public :: process_stack_t
```

⟨Process stacks: types⟩+≡
```
    type :: process_stack_t
       integer :: n = 0
       type(process_entry_t), pointer :: first => null ()
       type(var_list_t), pointer :: var_list => null ()
     contains
     ⟨Process stacks: process stack: TBP⟩
    end type process_stack_t
```

Finalizer. Iteratively deallocate the stack entries. The resulting empty stack can be immediately recycled, if necessary.

⟨Process stacks: process stack: TBP⟩≡
```
    procedure :: final => process_stack_final
```

⟨Process stacks: procedures⟩≡
```
    subroutine process_stack_final (object)
      class(process_stack_t), intent(inout) :: object
      type(process_entry_t), pointer :: process
      if (associated (object%var_list)) then
         call var_list_final (object%var_list)
         deallocate (object%var_list)
      end if
      do while (associated (object%first))
         process => object%first
         object%first => process%next
         call process%final ()
         deallocate (process)
      end do
      object%n = 0
    end subroutine process_stack_final
```

Output. The processes on the stack will be ordered LIFO, i.e., backwards.

⟨Process stacks: process stack: TBP⟩+≡
```
    procedure :: write => process_stack_write
```

⟨*Process stacks: procedures*⟩+≡

```
subroutine process_stack_write (object, unit, pacify)
  class(process_stack_t), intent(in) :: object
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: pacify
  type(process_entry_t), pointer :: process
  integer :: u
  u = output_unit (unit)
  call write_separator_double (u)
  select case (object%n)
  case (0)
     write (u, "(1x,A)")  "Process stack: [empty]"
     call write_separator_double (u)
  case default
     write (u, "(1x,A)")  "Process stack:"
     process => object%first
     do while (associated (process))
        call process%write (.false., u, pacify = pacify)
        process => process%next
     end do
  end select
end subroutine process_stack_write
```

The variable list is printed by a separate routine, since it should be linked to the global variable list, anyway.

⟨*Process stacks: process stack: TBP*⟩+≡

```
procedure :: write_var_list => process_stack_write_var_list
```

⟨*Process stacks: procedures*⟩+≡

```
subroutine process_stack_write_var_list (object, unit)
  class(process_stack_t), intent(in) :: object
  integer, intent(in), optional :: unit
  if (associated (object%var_list)) then
     call var_list_write (object%var_list, unit)
  end if
end subroutine process_stack_write_var_list
```

Short output.

⟨*Process stacks: process stack: TBP*⟩+≡

```
procedure :: show => process_stack_show
```

⟨*Process stacks: procedures*⟩+≡

```
subroutine process_stack_show (object, unit)
  class(process_stack_t), intent(in) :: object
  integer, intent(in), optional :: unit
  type(process_entry_t), pointer :: process
  integer :: u
  u = output_unit (unit)
  select case (object%n)
  case (0)
  case default
     process => object%first
     do while (associated (process))
        call process%show (u, verbose=.false.)
```

```
          process => process%next
        end do
      end select
    end subroutine process_stack_show
```

15.6.3   Push

We take a process pointer and push it onto the stack. The previous pointer is nullified. Subsequently, the process is 'owned' by the stack and will be finalized when the stack is deleted.

⟨*Process stacks: process stack: TBP*⟩+≡
```
    procedure :: push => process_stack_push
```

⟨*Process stacks: procedures*⟩+≡
```
    subroutine process_stack_push (stack, process)
      class(process_stack_t), intent(inout) :: stack
      type(process_entry_t), intent(inout), pointer :: process
      process%next => stack%first
      stack%first => process
      process => null ()
      stack%n = stack%n + 1
    end subroutine process_stack_push
```

Initialize the process variable list and link it to a global variable list.

⟨*Process stacks: process stack: TBP*⟩+≡
```
    procedure :: init_var_list => process_stack_init_var_list
```

⟨*Process stacks: procedures*⟩+≡
```
    subroutine process_stack_init_var_list (stack, var_list)
      class(process_stack_t), intent(inout) :: stack
      type(var_list_t), intent(inout), optional :: var_list
      allocate (stack%var_list)
      if (present (var_list))  call var_list_link (var_list, stack%var_list)
    end subroutine process_stack_init_var_list
```

Initialize process variables for a given process ID, without setting values.

⟨*Process stacks: process stack: TBP*⟩+≡
```
    procedure :: init_result_vars => process_stack_init_result_vars
```

⟨*Process stacks: procedures*⟩+≡
```
    subroutine process_stack_init_result_vars (stack, id)
      class(process_stack_t), intent(inout) :: stack
      type(string_t), intent(in) :: id
      call var_list_init_num_id (stack%var_list, id)
      call var_list_init_process_results (stack%var_list, id)
    end subroutine process_stack_init_result_vars
```

Fill process variables with values. This is executed after the integration pass.

  Note: We set only integral and error. With multiple MCI records possible, the results for `n_calls`, `chi2` etc. are not necessarily unique. (We might set the efficiency, though.)

⟨*Process stacks: process stack: TBP*⟩+≡

```
      procedure :: fill_result_vars => process_stack_fill_result_vars
```

⟨*Process stacks: procedures*⟩+≡
```
    subroutine process_stack_fill_result_vars (stack, id)
      class(process_stack_t), intent(inout) :: stack
      type(string_t), intent(in) :: id
      type(process_t), pointer :: process
      process => stack%get_process_ptr (id)
      if (associated (process)) then
         call var_list_init_num_id (stack%var_list, id, process%get_num_id ())
         if (process%has_integral ()) then
            call var_list_init_process_results (stack%var_list, id, &
                 integral = process%get_integral (), &
                 error = process%get_error ())
         end if
      else
         call msg_bug ("process_stack_fill_result_vars: unknown process ID")
      end if
    end subroutine process_stack_fill_result_vars
```

15.6.4 Data Access

Tell if a process exists.

⟨*Process stacks: process stack: TBP*⟩+≡
```
    procedure :: exists => process_stack_exists
```

⟨*Process stacks: procedures*⟩+≡
```
    function process_stack_exists (stack, id) result (flag)
      class(process_stack_t), intent(in) :: stack
      type(string_t), intent(in) :: id
      logical :: flag
      type(process_t), pointer :: process
      process => stack%get_process_ptr (id)
      flag = associated (process)
    end function process_stack_exists
```

Return a pointer to a process with specific ID.

⟨*Process stacks: process stack: TBP*⟩+≡
```
    procedure :: get_process_ptr => process_stack_get_process_ptr
```

⟨*Process stacks: procedures*⟩+≡
```
    function process_stack_get_process_ptr (stack, id) result (ptr)
      class(process_stack_t), intent(in) :: stack
      type(string_t), intent(in) :: id
      type(process_t), pointer :: ptr
      type(process_entry_t), pointer :: entry
      ptr => null ()
      entry => stack%first
      do while (associated (entry))
         if (entry%get_id () == id) then
            ptr => entry%process_t
            return
         end if
```

```
        entry => entry%next
      end do
    end function process_stack_get_process_ptr
```

15.6.5   Unit tests

⟨*Process stacks: public*⟩+≡
```
    public :: process_stacks_test
```

⟨*Process stacks: tests*⟩≡
```
    subroutine process_stacks_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
```
⟨*Process stacks: execute tests*⟩
```
    end subroutine process_stacks_test
```

Write an empty process stack

The most trivial test is to write an uninitialized process stack.

⟨*Process stacks: execute tests*⟩≡
```
    call test (process_stacks_1, "process_stacks_1", &
        "write an empty process stack", &
        u, results)
```

⟨*Process stacks: tests*⟩+≡
```
    subroutine process_stacks_1 (u)
      integer, intent(in) :: u
      type(process_stack_t) :: stack

      write (u, "(A)")  "* Test output: process_stacks_1"
      write (u, "(A)")  "*   Purpose: display an empty process stack"
      write (u, "(A)")

      call stack%write (u)

      write (u, "(A)")
      write (u, "(A)")  "* Test output end: process_stacks_1"

    end subroutine process_stacks_1
```

Fill a process stack

Fill a process stack with two (identical) processes.

⟨*Process stacks: execute tests*⟩+≡
```
    call test (process_stacks_2, "process_stacks_2", &
        "fill a process stack", &
        u, results)
```

⟨*Process stacks: tests*⟩+≡

```fortran
    subroutine process_stacks_2 (u)
      integer, intent(in) :: u
      type(process_stack_t) :: stack
      type(process_library_t), target :: lib
      type(string_t) :: libname
      type(string_t) :: procname
      type(string_t) :: run_id
      type(os_data_t) :: os_data
      type(qcd_t) :: qcd
      class(rng_factory_t), allocatable :: rng_factory
      type(model_list_t) :: model_list
      type(process_entry_t), pointer :: process => null ()

      write (u, "(A)")  "* Test output: process_stacks_2"
      write (u, "(A)")  "*   Purpose: fill a process stack"
      write (u, "(A)")

      write (u, "(A)")  "* Build, initialize and store two test processes"
      write (u, "(A)")

      libname = "process_stacks2"
      procname = libname
      call os_data_init (os_data)

```

Chapter 16

Parton shower and interface to hadronization

This is the code for the WHIZARD QCD parton shower for final state radiation (FSR) and initial state radiation (ISR) as well as the interface to the PYTHIA module for showering and hadronization.

⟨*Version*⟩≡

```
  contains
```
  ⟨*Shower base: procedures*⟩
```
  end module shower_base
```

### 16.1.1   PDF Interface of the shower

⟨*Shower base: public*⟩≡
```
    public :: shower_pdf
```

⟨*Shower base: interfaces*⟩≡
```
    interface
      subroutine shower_pdf (set, x, q, ff)
        integer, intent(in) :: set
        double precision, intent(in) :: x, q
        double precision, dimension(-6:6), intent(out) :: ff
      end subroutine shower_pdf
```

```
    end interface
```

16.1.2 Parameters

This decides whether to print out additional information.

⟨*Shower base: parameters*⟩≡
```
    logical, parameter, public :: D_print = .false.
```

These parameters are the cut-off scale t_{cut}, given in GeV^2 (`PARJ(82)`), the cut-off scale for the P_t^2-ordered shower in GeV^2, and the two shower parameters `PARP(72)` and `PARP(61)`, respectively.

⟨*Shower base: parameters*⟩+≡
```
    real(default), public :: D_Min_t = one
    real(default), public :: D_min_scale = 0.5_default
    real(default), public :: D_Lambda_fsr = 0.29_default
    real(default), public :: D_Lambda_isr = 0.29_default
```

The parameter `MSTJ(45)` gives the maximum number of flavours in gluon decay to quarks:

⟨*Shower base: parameters*⟩+≡
```
    integer, public :: D_Nf = 5
```

These two parameters decide whether to use constant or running $alpha_s$ in the form of the function $D\_alpha_s(t)$ for the FSR and ISR (`MSTJ(44)`, `MSTP(64)`), respectively. The next is the parameter `PARU(111)`, which sets the value for constant α_s, and the flag whether to use P_t-ordered ISR.

⟨*Shower base: parameters*⟩+≡
```
    logical, public :: D_running_alpha_s_fsr = .true.
    logical, public :: D_running_alpha_s_isr = .true.
    real(default), public :: D_constalpha_s = 0.20_default
    logical, public :: isr_pt_ordered = .false.
```

This flag sets emitted timelike partons in the spacelike shower on shell, true corresponds to `MSTP(63)` = 0.

⟨*Shower base: parameters*⟩+≡
```
    logical, public :: isr_only_onshell_emitted_partons = .true.
```

Flag whether ISR is angular ordered (`MSTP(62)`).

⟨*Shower base: parameters*⟩+≡
```
    logical, public :: isr_angular_ordered = .true.
```

Treating either u and d, or all quarks except t as massless:

⟨*Shower base: parameters*⟩+≡
```
    logical, public :: treat_light_quarks_massless = .true.
    logical, public :: treat_duscb_quarks_massless = .false.
```

The width and the cutoff of the Gaussian primordial k_t distribution, `PARP(91)` and `PARP(93)`, in GeV:

⟨*Shower base: parameters*⟩+≡
```
    real(default), public :: primordial_kt_width = 1.5_default
    real(default), public :: primordial_kt_cutoff = five
```

The parameter `PARP(66)`, the minimal energy of the emitted timelike parton in the ISR (`PARP(65)`), the factor for the first scale, as well as the factor by which the integral in the Sudakhov factor is suppressed for the respective first scale in ISR. Higher values here correspond to higher starting scales.

⟨*Shower base: parameters*⟩+≡
```
real(default), public :: maxz_isr = 0.999_default
real(default), public :: minenergy_timelike = one
real(default), public :: tscalefactor_isr = one
real(default), public :: first_integral_suppression_factor = one
```

Temporary parameters for the P_t-ordered shower:

⟨*Shower base: parameters*⟩+≡
```
real(default), public :: scalefactor1 = 0.02_default
real(default), public :: scalefactor2 = 0.02_default
```

Then, there are the variables for the PDF functions:

⟨*Shower base: parameters*⟩+≡
```
integer, public :: shower_pdf_set = 0
```

And the PDF function itself, as a procedure pointer:

⟨*Shower base: parameters*⟩+≡
```
procedure(shower_pdf), pointer, public :: shower_pdf_func
```

⟨*Shower base: procedures*⟩≡
```
subroutine randomseed (seed)
  integer, intent(in), optional :: seed
  integer :: clock

  if (present (seed)) then
     clock = seed
  else
     call system_clock (count = clock)
  end if
  call tao_random_seed (clock)
end subroutine randomseed
```

⟨*Shower base: public*⟩+≡
```
public :: D_alpha_s_isr
public :: D_alpha_s_fsr
```

⟨*Shower base: procedures*⟩+≡
```
function D_alpha_s_isr (tin) result(alpha_s)
  real(default), intent(in) :: tin
  real(default) :: b, t
  real(default) :: alpha_s

!    arbitrary lower cut off for scale
!    t = MAX(max(one * D_Min_t, 1.1_default * D_Lambda_isr**2), ABS(tin))
  t = max (max (0.1_default * D_Min_t, &
        1.1_default * D_Lambda_isr**2), abs(tin))

  if (D_running_alpha_s_isr) then
     b = (33._default - two * number_of_flavors(t)) / (12._default * pi)
     alpha_s = one / (b * log(t / (D_Lambda_isr**2)))
```

2146

```
      else
         alpha_s = D_constalpha_s
      end if
   end function D_alpha_s_isr

   function D_alpha_s_fsr (tin) result(alpha_s)
     real(default), intent(in) :: tin
     real(default) :: b, t
     real(default) :: alpha_s

 !   arbitrary lower cut off for scale
 !   t= max( max (one * D_Min_t, 1.1_default * D_Lambda**2), ABS(tin))
     t = max (max (0.1_default * D_Min_t, &
          1.1_default * D_Lambda_fsr**2), abs(tin))

     if (D_running_alpha_s_fsr) then
        b = (33._default - two * number_of_flavors(t)) / (12._default * pi)
        alpha_s = one / (b * log(t / (D_Lambda_fsr**2)))
     else
        alpha_s = D_constalpha_s
     end if
   end function D_alpha_s_fsr
```

Mass and mass squared selection functions. All masses are in GeV. Light quarks are assumed to be ordered, $m_1 < m_2 < m_3 \ldots$, and they get current masses, not elementary ones. Mesons and baryons other than proton and neutron are needed as beam-remnants. Particles with PDG number zero are taken massless, as well as proper beam remnants and any other particles.

16.2.1 The basic type defintions

The type `parton_t` defines a parton for the shower. The `x` value of the parton is only needed for spacelike showers. The pointer `initial` is only needed for partons in initial showers, it points to the hadron the parton is coming from. An auxiliary value for the P_t-ordered ISR is `aux_pt`. Then, there are two auxiliary entries for the clustering of CKKW pseudo weights and CKKW matching, `ckkwlabel` and `ckkwscale`.

⟨*Shower partons: public*⟩≡
```
    public :: parton_t
```
⟨*Shower partons: types*⟩≡
```
    type :: parton_t
       integer :: nr = 0
       integer :: type = 0
       type(vector4_t) :: momentum = vector4_null
       real(default) :: t  = zero
       real(default) :: scale = zero
       real(default) :: z = zero
       real(default) :: costheta = zero
       real(default) :: x = zero
       logical :: simulated = .false.
       logical :: belongstoFSR = .true.
       logical :: belongstointeraction = .false.
       type(parton_t), pointer :: parent => null ()
       type(parton_t), pointer :: child1 => null ()
       type(parton_t), pointer :: child2 => null ()
       type(parton_t), pointer :: initial => null ()
       integer :: c1 = 0, c2 = 0
       integer :: aux_pt = 0
       integer :: ckkwlabel = 0
       real(default) :: ckkwscale = zero
       integer :: ckkwtype = -1
       integer :: interactionnr = 0
    end type parton_t
```

⟨*Shower partons: public*⟩+≡
```
    public :: parton_pointer_t
```
⟨*Shower partons: types*⟩+≡
```
    type :: parton_pointer_t
       type(parton_t), pointer :: p => null ()
    end type parton_pointer_t
```

16.2.2 Routines

⟨*Shower partons: public*⟩+≡
```
    public :: parton_copy
```

⟨Shower partons: procedures⟩≡
```
    subroutine parton_copy (prt1, prt2)
      type(parton_t), intent(in) :: prt1
      type(parton_t), intent(out) :: prt2
      prt2%nr = prt1%nr
      prt2%type = prt1%type
      prt2%momentum = prt1%momentum
      prt2%t = prt1%t
      prt2%scale = prt1%scale
      prt2%z = prt1%z
      prt2%costheta = prt1%costheta
      prt2%x = prt1%x
      prt2%simulated = prt1%simulated
      prt2%belongstoFSR = prt1%belongstoFSR
      prt2%belongstointeraction = prt1%belongstointeraction
      prt2%interactionnr = prt1%interactionnr
      if (associated (prt1%parent))  prt2%parent  => prt1%parent
      if (associated (prt1%child1))  prt2%child1  => prt1%child1
      if (associated (prt1%child2))  prt2%child2  => prt1%child2
      if (associated (prt1%initial)) prt2%initial => prt1%initial
      prt2%c1 = prt1%c1
      prt2%c2 = prt1%c2
      prt2%aux_pt = prt1%aux_pt
    end subroutine parton_copy
```

This returns the angle between the daughters assuming them to be massless.

⟨Shower partons: public⟩+≡
```
    public :: parton_get_costheta
```

⟨Shower partons: procedures⟩+≡
```
    function parton_get_costheta (prt) result (costheta)
      type(parton_t), intent(in) :: prt
      real(default) :: costheta
      if (prt%z * (one - prt%z) * parton_get_energy(prt)**2 > zero) then
         costheta = one - prt%t / (two * prt%z * (one - prt%z) * &
               parton_get_energy(prt)**2)
      else
         costheta = - one
      end if
    end function parton_get_costheta
```

The same for massive daughters.

⟨Shower partons: public⟩+≡
```
    public :: parton_get_costheta_correct
```

⟨Shower partons: procedures⟩+≡
```
    function parton_get_costheta_correct (prt) result (costheta)
      type(parton_t), intent(in) :: prt
      real(default) :: costheta

  ⟨*Standard module head*⟩

  ⟨*Shower core: public*⟩

  ⟨*Shower core: parameters*⟩

  ⟨*Shower core: types*⟩

```
  contains
```

  ⟨*Shower core: procedures*⟩

```
  end module shower_core
```

⟨*Shower core: public*⟩≡
```
    public :: shower_interaction_t
```
⟨*Shower core: types*⟩≡
```
    type :: shower_interaction_t
       type(parton_pointer_t), dimension(:), allocatable :: partons
    end type shower_interaction_t

    type :: shower_interaction_pointer_t
       type(shower_interaction_t), pointer :: i => null ()
    end type shower_interaction_pointer_t
```

The main type of `shower_core`:

⟨*Shower core: public*⟩+≡
```
    public :: shower_t
```

⟨*Shower core: types*⟩+≡
```
    type :: shower_t
       type(shower_interaction_pointer_t), dimension(:), allocatable :: &
            interactions
       type(parton_pointer_t), dimension(:), allocatable :: partons
       integer :: next_free_nr
       integer :: next_color_nr
       logical :: valid
     contains
     ⟨Shower core: shower: TBP⟩
    end type shower_t
```

The parameters of the shower module:

⟨*Shower core: parameters*⟩≡
```
    ! real(default), parameter :: alphasmax = one
    ! real(default), parameter :: xpdfmax = 10._default
    real(default), save :: alphasxpdfmax = 12._default
```

⟨*Shower core: shower: TBP*⟩≡
```
    procedure :: add_interaction_2ton => shower_add_interaction_2ton
```

⟨*Shower core: procedures*⟩≡
```
    subroutine shower_add_interaction_2ton (shower, partons)
      class(shower_t), intent(inout) :: shower
      type(parton_pointer_t), intent(in), dimension(:), allocatable :: partons
      type(ckkw_pseudo_shower_weights_t) :: ckkw_pseudo_weights
      call shower%add_interaction_2ton_CKKW (partons, ckkw_pseudo_weights)
    end subroutine shower_add_interaction_2ton
```

In this routine, `y` and `ymin` are the jet measures, `w` and `wmax` are weights, `s` is the kinematic energy squared of the interaction. The flag `isr_is_possible` checks whether the initial parton is set, lepton-hadron collisions are not implemented (yet). As a workaround: as WHIZARD can treat partons as massless, there might be partons with $E < m$: if such a parton is found, quarks will be treated massless.

⟨*Shower core: shower: TBP*⟩+≡
```
    procedure :: add_interaction_2ton_CKKW => shower_add_interaction_2ton_CKKW
```

⟨*Shower core: procedures*⟩+≡
```
    subroutine shower_add_interaction_2ton_CKKW &

  !C      KTCLUS: written by Mike Seymour, July 1992.
  !C      Last modified November 2000.
  !C      Please send comments or suggestions to Mike.Seymour@rl.ac.uk
  !C
  !C      This is a general-purpose kt clustering package.
  !C      It can handle ee, ep and pp collisions.
  !C      It is loosely based on the program of Siggi Bethke.
  !C
  !C      The time taken (on a 10MIP machine) is (0.2microsec)*N**3
  !C      where N is the number of particles.
  !C      Over 90 percent of this time is used in subroutine KTPMIN, which
  !C      simply finds the minimum member of a one-dimensional array.
  !C      It is well worth thinking about optimization: on the SPARCstation
  !C      a factor of two increase was obtained simply by increasing the
  !C      optimization level from its default value.
  !C
  !C      The approach is to separate the different stages of analysis.
  !C      KTCLUS does all the clustering and records a merging history.
  !C      It returns a simple list of the y values at which each merging
  !C      occured. Then the following routines can be called to give extra
  !C      information on the most recently analysed event.
  !C      KTCLUR is identical but includes an R parameter, see below.
  !C      KTYCUT gives the number of jets at each given YCUT value.
  !C      KTYSUB gives the number of sub-jets at each given YCUT value.
  !C      KTBEAM gives same info as KTCLUS but only for merges with the beam
  !C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.
  !C      KTRECO reconstructs the jet momenta at a given value of YCUT.
  !C      It also gives information on which jets at scale YCUT belong to
  !C      which macro-jets at scale YMAC, for studying sub-jet properties.
  !C      KTINCL reconstructs the jet momenta according to the inclusive jet
  !C      definition of Ellis and Soper.
  !C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,
  !C      except that they only apply to one inclusive jet at a time,
  !C      with the pt of that jet automatically used for ECUT.
  !C      KTWICH gives a list of which particles ended up in which jets.
  !C      KTWCHS gives the same thing, but only for subjets.
  !C      Note that the numbering of jets used by these two routines is
  !C      guaranteed to be the same as that used by KTRECO.
  !C
  !C      The collision type and analysis type are indicated by the first
  !C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where
  !C      TYPE:  1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
  !C      ANGLE: 1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
  !C             where f()=2(cosh(eta)-cos(phi)) is the QCD emission metric
  !C      MONO:  1=>derive relative pseudoparticle angles from jets
  !C             2=>monotonic definitions of relative angles
  !C      RECOM: 1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
  !C
```

```
!C     There are also abbreviated forms for the most common combinations:
!C     IMODE=1 => E scheme in e+e-                        (=1111)
!C          2 => E scheme in ep                           (=2111)
!C          3 => E scheme in pe                           (=3111)
!C          4 => E scheme in pp                           (=4111)
!C          5 => covariant E scheme in pp                 (=4211)
!C          6 => covariant pt-scheme in pp                (=4212)
!C          7 => covariant monotonic pt**2-scheme in pp   (=4223)
!C
!C     KTRECO no longer needs to reconstruct the momenta according to the
!C     same recombination scheme in which they were clustered. Its first
!C     argument gives the scheme, taking the same values as RECOM above.
!C
!C     Note that unlike previous versions, all variables which hold y
!C     values have been named in a consistent way:
!C     Y()  is the output scale at which jets were merged,
!C     YCUT is the input scale at which jets should be counted, and
!C          jet-momenta reconstructed etc,
!C     YMAC is the input macro-jet scale, used in determining whether
!C          or not each jet is a sub-jet.
!C     The original scheme defined in our papers is equivalent to always
!C     setting YMAC=1.
!C     Whenever a YCUT or YMAC variable is used, it is rounded down
!C     infinitesimally, so that for example, setting YCUT=Y(2) refers
!C     to the scale where the event is 2-jet, even if rounding errors
!C     have shifted its value slightly.
!C
!C     An R parameter can be used in hadron-hadron collisions by
!C     calling KTCLUR instead of KTCLUS.  This is as suggested by
!C     Ellis and Soper, but implemented slightly differently,
!C     as in M.H. Seymour, LU TP 94/2 (submitted to Nucl. Phys. B.).
!C     R**2 multiplies the single Kt everywhere it is used.
!C     Calling KTCLUR with R=1 is identical to calling KTCLUS.
!C     R plays a similar role to the jet radius in a cone-type algorithm,
!C     but is scaled up by about 40% (ie R=0.7 in a cone algorithm is
!C     similar to this algorithm with R=1).
!C     Note that R.EQ.1 must be used for the e+e- and ep versions,
!C     and is strongly recommended for the hadron-hadron version.
!C     However, R values smaller than 1 have been found to be useful for
!C     certain applications, particularly the mass reconstruction of
!C     highly-boosted colour-singlets such as high-pt hadronic Ws,
!C     as in M.H. Seymour, LU TP 93/8 (to appear in Z. Phys. C.).
!C     Situations in which R<1 is useful are likely to also be those in
!C     which the inclusive reconstruction method is more useful.
!C
!C     Also included is a set of routines for doing Lorentz boosts:
!C     KTLBST finds the boost matrix to/from the cm frame of a 4-vector
!C     KTRROT finds the rotation matrix from one vector to another
!C     KTMMUL multiplies together two matrices
!C     KTVMUL multiplies a vector by a matrix
!C     KTINVT inverts a transformation matrix (nb NOT a general 4 by 4)
!C     KTFRAM boosts a list of vectors between two arbitrary frames
!C     KTBREI boosts a list of vectors between the lab and Breit frames
!C     KTHADR boosts a list of vectors between the lab and hadronic cmf
```

```
!C        The last two need the momenta in the +z direction of the lepton
!C        and hadron beams, and the 4-momentum of the outgoing lepton.
!C
!C    The main reference is:
!C       S. Catani, Yu.L. Dokshitzer, M.H. Seymour and B.R. Webber,
!C          Nucl.Phys.B406(1993)187.
!C    The ep version was proposed in:
!C       S. Catani, Yu.L. Dokshitzer and B.R. Webber,
!C          Phys.Lett.285B(1992)291.
!C    The inclusive reconstruction method was proposed in:
!C       S.D. Ellis and D.E. Soper,
!C          Phys.Rev.D48(1993)3160.

CKKW (pseudo) weights

The type `ckkw_pseudo_shower_weights_t` gives the (relative) weights for different clusterings of the final particles, as given in Eq. (2.7) of hep-ph/0503281v1. Each particle has a binary labelling (power of 2) (first particle = 1, second particle = 2, third particle = 4, ...). Each recombination therefore corresponds to an integer, that is not a power of 2. Fur multiple subsequent recombinations, no different weights for different sequences of clustering are stored. It is assumed that the weight of a multiply recombined state is a combination of the states with one fewer recombination and that these states' contributions are proportional to their weights. For a $2->n$ event, the weights array thus has the size $2^{(2+n)-1}$. The `weights_by_type` array gives the weights depending on the type of the particle, the first index is the same as for weights, the second index gives the type of the new mother particle:

0: uncolored (γ, Z, W, Higgs)

1: colored (quark)

2: gluon

3: squark

4: gluino

alphaS gives the value for $alpha_s$ used in the generation of the matrix element. This is needed for the reweighting using the values for a running $alpha_s$ at the scales of the clusterings.

Chapter 17

Events

With a process object and the associated methods at hand, we can generate events for elementary processes and, by subsequent transformation, for complete physical processes.

We have the following modules:

event_transforms Abstract base type for transforming a physical process with process instance and included evaluators, etc., into a new object. The following modules extend this base type.

decays Combine the elementary process with elementary decay processes and thus transform the elementary event into a decayed event, still at the parton level.

showers (not re-activated yet) Create QED/QCD showers out of the partons that are emitted by elementary processes. This should be interleaved with showering of radiated particles (structure functions) and multiple interactions.

hadrons (not implemented yet) Apply hadronization to the partonic events, interleaved with hadron decays. (The current setup relies on hadronizing partonic events externally.)

events Combine all pieces to generate full events.

17.1 Abstract Event Transforms

⟨`event_transforms.f90`⟩≡

    use processes
    use process_stacks
```

⟨*Standard module head*⟩

⟨*Event transforms: public*⟩

⟨*Event transforms: types*⟩

⟨*Event transforms: interfaces*⟩

```
contains
```

⟨*Event transforms: procedures*⟩

⟨*Event transforms: tests*⟩

```
end module event_transforms
```

17.1.1   Abstract base type

Essentially, all methods are abstract, but some get minimal base versions. We know that there will be a random-number generator at top level, and that we will relate to an elementary process.

The model is stored separately. It may contain modified setting that differ from the model instance stored in the process object.

Each event transform contains a particle set that it can fill for further use. There is a flag the indicates this.

We will collect event transforms in a list, therefore we include a `previous` and `next` pointers.

⟨*Event transforms: public*⟩≡
```
    public :: evt_t
```

⟨*Event transforms: types*⟩≡
```
    type, abstract :: evt_t
       type(process_t), pointer :: process => null ()
       type(process_instance_t), pointer :: process_instance => null ()
       type(model_t), pointer :: model => null ()
```

```
      class(rng_t), allocatable :: rng
      integer :: rejection_count = 0
      logical :: particle_set_exists = .false.
      type(particle_set_t) :: particle_set
      class(evt_t), pointer :: previous => null ()
      class(evt_t), pointer :: next => null ()
   contains
   ⟨Event transforms: evt: TBP⟩
   end type evt_t
```

Finalizer. In any case, we finalize the r.n.g. The process instance is a pointer and should not be finalized here.

⟨*Event transforms: evt: TBP*⟩≡
```
    procedure :: final => evt_final
    procedure :: base_final => evt_final
```

⟨*Event transforms: procedures*⟩≡
```
    subroutine evt_final (object)
      class(evt_t), intent(inout) :: object
      if (allocated (object%rng))  call object%rng%final ()
      if (object%particle_set_exists) &
           call particle_set_final (object%particle_set)
    end subroutine evt_final
```

Output. We can print r.n.g. info.

⟨*Event transforms: evt: TBP*⟩+≡
```
    procedure :: base_write => evt_write
```

⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_write (object, unit, verbose, testflag)
      class(evt_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose, testflag
      integer :: u
      u = output_unit (unit)
      if (associated (object%process)) then
         write (u, "(3x,A,A,A)")   "Associated process: '", &
              char (object%process%get_id ()), "'"
      end if
      if (allocated (object%rng)) then
         call object%rng%write (u, 1)
         write (u, "(3x,A,I0)")   "Number of tries = ", object%rejection_count
      end if
      if (object%particle_set_exists) then
         call write_separator (u)
         call particle_set_write (object%particle_set, u, testflag)
      end if
    end subroutine evt_write
```

Connect the transform with a process instance (and thus with the associated process). Use this to allocate the master random-number generator.

This is not an initializer; we may initialize the transform by implementation-specific methods.

⟨*Event transforms: evt: TBP*⟩+≡
```
    procedure :: connect => evt_connect
    procedure :: base_connect => evt_connect
```

⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_connect (evt, process_instance, model, process_stack)
      class(evt_t), intent(inout), target :: evt
      type(process_instance_t), intent(in), target :: process_instance
      type(model_t), intent(in), target :: model
      type(process_stack_t), intent(in), optional :: process_stack
      evt%process => process_instance%process
      evt%process_instance => process_instance
      evt%model => model
      call evt%process%make_rng (evt%rng)
    end subroutine evt_connect
```

Reset internal state.

⟨*Event transforms: evt: TBP*⟩+≡
```
    procedure :: reset => evt_reset
    procedure :: base_reset => evt_reset
```

⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_reset (evt)
      class(evt_t), intent(inout) :: evt
      evt%rejection_count = 0
      evt%particle_set_exists = .false.
    end subroutine evt_reset
```

Prepare for a new event: reset internal state, if necessary. We provide MCI and term index of the parent process.

⟨*Event transforms: evt: TBP*⟩+≡
```
    procedure (evt_prepare_new_event), deferred :: prepare_new_event
```

⟨*Event transforms: interfaces*⟩≡
```
    interface
       subroutine evt_prepare_new_event (evt, i_mci, i_term)
         import
         class(evt_t), intent(inout) :: evt
         integer, intent(in) :: i_mci, i_term
       end subroutine evt_prepare_new_event
    end interface
```

Generate a weighted event, using a valid initiator event in the process instance, and the random-number generator. The returned event probability should be a number between zero and one that we can use for rejection.

⟨*Event transforms: evt: TBP*⟩+≡
```
    procedure (evt_generate_weighted), deferred :: generate_weighted
```

⟨*Event transforms: interfaces*⟩+≡
```
    abstract interface
       subroutine evt_generate_weighted (evt, probability)
```

```
        import
        class(evt_t), intent(inout) :: evt
        real(default), intent(out) :: probability
      end subroutine evt_generate_weighted
    end interface
```

The unweighted event generation routine is actually implemented. It uses the random-number generator for simple rejection. Of course, the implementation may override this and implement a different way of generating an unweighted event.

⟨*Event transforms: evt: TBP*⟩+≡
```
    procedure :: generate_unweighted => evt_generate_unweighted
    procedure :: base_generate_unweighted => evt_generate_unweighted
```

⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_generate_unweighted (evt)
      class(evt_t), intent(inout) :: evt
      real(default) :: p, x
      evt%rejection_count = 0
      REJECTION: do
         evt%rejection_count = evt%rejection_count + 1
         call evt%generate_weighted (p)
         if (signal_is_pending ())  return
         call evt%rng%generate (x)
         if (x < p)  exit REJECTION
      end do REJECTION
    end subroutine evt_generate_unweighted
```

Make a particle set. This should take the most recent evaluator (or whatever stores the event), factorize the density matrix if necessary, and store as a particle set.

If applicable, the factorization should make use of the `factorization_mode` and `keep_correlations` settings.

The values **r**, if set, should control the factorization in more detail, e.g., bypassing the random-number generator.

⟨*Event transforms: evt: TBP*⟩+≡
```
    procedure (evt_make_particle_set), deferred :: make_particle_set
```

⟨*Event transforms: interfaces*⟩+≡
```
    interface
      subroutine evt_make_particle_set &
           (evt, factorization_mode, keep_correlations, r)
        import
        class(evt_t), intent(inout) :: evt
        integer, intent(in) :: factorization_mode
        logical, intent(in) :: keep_correlations
        real(default), dimension(:), intent(in), optional :: r
      end subroutine evt_make_particle_set
    end interface
```

Copy an existing particle set into the event record. This bypasses all methods to evaluate the internal state, but may be sufficient for further processing.

⟨*Event transforms: evt: TBP*⟩+≡

```
        procedure :: set_particle_set => evt_set_particle_set
```
⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_set_particle_set (evt, particle_set, i_mci, i_term)
      class(evt_t), intent(inout) :: evt
      type(particle_set_t), intent(in) :: particle_set
      integer, intent(in) :: i_term, i_mci
      call evt%prepare_new_event (i_mci, i_term)
      evt%particle_set = particle_set
      evt%particle_set_exists = .true.
    end subroutine evt_set_particle_set
```

This procedure can help in the previous task, if the particles are available in
the form of an interaction object. (We need two interactions, one with color
summed over, and one with the probability distributed among flows.)

  We use the two values from the random number generator for factorizing the
state. For testing purposes, we can provide those numbers explicitly.

⟨*Event transforms: evt: TBP*⟩+≡
```
    procedure :: factorize_interactions => evt_factorize_interactions
```
⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_factorize_interactions &
        (evt, int_matrix, int_flows, factorization_mode, keep_correlations, r)
      class(evt_t), intent(inout) :: evt
      type(interaction_t), intent(in), target :: int_matrix, int_flows
      integer, intent(in) :: factorization_mode
      logical, intent(in) :: keep_correlations
      real(default), dimension(:), intent(in), optional :: r
      real(default), dimension(2) :: x
      if (present (r)) then
         if (size (r) == 2) then
            x = r
         else
            call msg_bug ("event factorization: size of r array must be 2")
         end if
      else
         call evt%rng%generate (x)
      end if
      call particle_set_init (evt%particle_set, evt%particle_set_exists, &
           int_matrix, int_flows, factorization_mode, x, &
           keep_correlations, keep_virtual=.true.)
      evt%particle_set_exists = .true.
    end subroutine evt_factorize_interactions
```

Mark the incoming particles as incoming in the particle set. This is necessary
because in the interaction objects they are usually marked as virtual.

  In the inquiry functions we set the term index to one; the indices of beams
and incoming particles should be identical for all process terms.

  We use the initial elementary process for obtaining the indices. Thus, we
implicitly assume that the beam and incoming indices stay the same across event
transforms. If this is not true for a transform (say, MPI), it should override this
method.

⟨*Event transforms: evt: TBP*⟩+≡

```
    procedure :: tag_incoming => evt_tag_incoming
```

⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_tag_incoming (evt)
      class(evt_t), intent(inout) :: evt
      integer :: i_term, n_in
      integer, dimension(:), allocatable :: beam_index, in_index
      n_in = evt%process%get_n_in ()
      i_term = 1
      allocate (beam_index (n_in))
      call evt%process_instance%get_beam_index (i_term, beam_index)
      call particle_set_reset_status (evt%particle_set, &
           beam_index, PRT_BEAM)
      allocate (in_index (n_in))
      call evt%process_instance%get_in_index (i_term, in_index)
      call particle_set_reset_status (evt%particle_set, &
           in_index, PRT_INCOMING)
    end subroutine evt_tag_incoming
```

17.1.2 Implementation: Trivial transform

This transform contains just a pointer to process and process instance. The
generate methods do nothing.

⟨*Event transforms: public*⟩+≡
```
    public :: evt_trivial_t
```

⟨*Event transforms: types*⟩+≡
```
    type, extends (evt_t) :: evt_trivial_t
     contains
     ⟨Event transforms: evt trivial: TBP⟩
    end type evt_trivial_t
```

The finalizer is trivial. Some output:

⟨*Event transforms: evt trivial: TBP*⟩≡
```
    procedure :: write => evt_trivial_write
```

⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_trivial_write (object, unit, verbose, testflag)
      class(evt_trivial_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose, testflag
      integer :: u
      u = output_unit (unit)
      call write_separator_double (u)
      write (u, "(1x,A)")  "Event transform: trivial (hard process)"
      call write_separator (u)
      call object%base_write (u, testflag = testflag)
    end subroutine evt_trivial_write
```

Nothing to do here:

⟨*Event transforms: evt trivial: TBP*⟩+≡
```
    procedure :: prepare_new_event => evt_trivial_prepare_new_event
```

⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_trivial_prepare_new_event (evt, i_mci, i_term)
      class(evt_trivial_t), intent(inout) :: evt
      integer, intent(in) :: i_mci, i_term
      call evt%reset ()
    end subroutine evt_trivial_prepare_new_event
```

The weighted generator is, surprisingly, trivial.

⟨*Event transforms: evt trivial: TBP*⟩+≡
```
    procedure :: generate_weighted => evt_trivial_generate_weighted
```

⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_trivial_generate_weighted (evt, probability)
      class(evt_trivial_t), intent(inout) :: evt
      real(default), intent(out) :: probability
      probability = 1
    end subroutine evt_trivial_generate_weighted
```

This routine makes a particle set, using the associated process instance as-is.

⟨*Event transforms: evt trivial: TBP*⟩+≡
```
    procedure :: make_particle_set => evt_trivial_make_particle_set
```

⟨*Event transforms: procedures*⟩+≡
```
    subroutine evt_trivial_make_particle_set &
        (evt, factorization_mode, keep_correlations, r)
      class(evt_trivial_t), intent(inout) :: evt
      integer, intent(in) :: factorization_mode
      logical, intent(in) :: keep_correlations
      real(default), dimension(:), intent(in), optional :: r
      integer :: i_term
      type(interaction_t), pointer :: int_matrix, int_flows
      if (evt%process_instance%is_complete_event ()) then
         call evt%process_instance%select_i_term (i_term)
         int_matrix => evt%process_instance%get_matrix_int_ptr (i_term)
         int_flows  => evt%process_instance%get_flows_int_ptr (i_term)
         call evt%factorize_interactions (int_matrix, int_flows, &
             factorization_mode, keep_correlations, r)
         call evt%tag_incoming ()
      else
         call msg_bug ("Event factorization: event is incomplete")
      end if
    end subroutine evt_trivial_make_particle_set
```

17.1.3 Unit tests

⟨*Event transforms: public*⟩+≡
```
    public :: event_transforms_test
```

⟨*Event transforms: tests*⟩≡
```
    subroutine event_transforms_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
```
⟨*Event transforms: execute tests*⟩

```
          end subroutine event_transforms_test
```

Test trivial event transform

The trivial transform, as an instance of the abstract transform, does nothing
but to trigger event generation for an elementary process.

⟨*Event transforms: execute tests*⟩≡
```
    call test (event_transforms_1, "event_transforms_1", &
         "trivial event transform", &
         u, results)
```

⟨*Event transforms: tests*⟩+≡
```
    subroutine event_transforms_1 (u)
      integer, intent(in) :: u
      type(os_data_t) :: os_data
      type(qcd_t) :: qcd
      class(rng_factory_t), allocatable :: rng_factory
      type(model_list_t) :: model_list
      type(model_t), pointer :: model
      type(process_library_t), target :: lib
      type(string_t) :: libname, procname1, run_id
      class(prc_core_t), allocatable :: core_template
      class(mci_t), allocatable :: mci_template
      class(phs_config_t), allocatable :: phs_config_template

```

17.2.1 Final-State Particle Configuration

A final-state particle may be either stable or unstable. Here is an empty abstract type as the parent of both, with holds just the flavor information.

⟨*Decays: types*⟩≡
```
    type, abstract :: any_config_t
     contains
     ⟨Decays: any config: TBP⟩
    end type any_config_t
```

Finalizer, depends on the implementation.

⟨*Decays: any config: TBP*⟩≡
```
    procedure (any_config_final), deferred :: final
```

⟨*Decays: interfaces*⟩≡
```
    interface
       subroutine any_config_final (object)
         import
         class(any_config_t), intent(inout) :: object
       end subroutine any_config_final
    end interface
```

The output is also deferred:

⟨*Decays: any config: TBP*⟩+≡
```
    procedure (any_config_write), deferred :: write
```

⟨*Decays: interfaces*⟩+≡
```
interface
   subroutine any_config_write (object, unit, indent, verbose)
     import
     class(any_config_t), intent(in) :: object
     integer, intent(in), optional :: unit, indent
     logical, intent(in), optional :: verbose
   end subroutine any_config_write
end interface
```

This is a container for a stable or unstable particle configurator. We need this wrapper for preparing arrays that mix stable and unstable particles.

⟨*Decays: types*⟩+≡
```
type :: particle_config_t
   class(any_config_t), allocatable :: c
end type particle_config_t
```

17.2.2   Final-State Particle

In theory, for the particle instance we only need to consider the unstable case. However, it is more straightforward to treat configuration and instance on the same footing, and to introduce a wrapper for particle objects as above. This also works around a compiler bug in gfortran.

⟨*Decays: types*⟩+≡
```
type, abstract :: any_t
 contains
 ⟨Decays: any: TBP⟩
end type any_t
```

Finalizer, depends on the implementation.

⟨*Decays: any: TBP*⟩≡
```
procedure (any_final), deferred :: final
```

⟨*Decays: interfaces*⟩+≡
```
interface
   subroutine any_final (object)
     import
     class(any_t), intent(inout) :: object
   end subroutine any_final
end interface
```

The output is also deferred:

⟨*Decays: any: TBP*⟩+≡
```
procedure (any_write), deferred :: write
```

⟨*Decays: interfaces*⟩+≡
```
interface
   subroutine any_write (object, unit, indent)
     import
     class(any_t), intent(in) :: object
     integer, intent(in), optional :: unit, indent
```

```
          end subroutine any_write
      end interface
```

This is a container for a stable or unstable outgoing particle. We need this wrapper for preparing arrays that mix stable and unstable particles.

⟨*Decays: types*⟩+≡
```
    type :: particle_out_t
       class(any_t), allocatable :: c
    end type particle_out_t
```

17.2.3 Decay Term Configuration

A decay term is a distinct final state, corresponding to a process term. Each decay process may give rise to several terms with, possibly, differing flavor content.

⟨*Decays: types*⟩+≡
```
    type :: decay_term_config_t
       type(particle_config_t), dimension(:), allocatable :: prt
     contains
     ⟨Decays: decay term config: TBP⟩
    end type decay_term_config_t
```

Finalizer, recursive.

⟨*Decays: decay term config: TBP*⟩≡
```
    procedure :: final => decay_term_config_final
```

⟨*Decays: procedures*⟩≡
```
    recursive subroutine decay_term_config_final (object)
      class(decay_term_config_t), intent(inout) :: object
      integer :: i
      if (allocated (object%prt)) then
         do i = 1, size (object%prt)
            if (allocated (object%prt(i)%c))  call object%prt(i)%c%final ()
         end do
      end if
    end subroutine decay_term_config_final
```

Output, with optional indentation

⟨*Decays: decay term config: TBP*⟩+≡
```
    procedure :: write => decay_term_config_write
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_term_config_write (object, unit, indent, verbose)
      class(decay_term_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
      integer :: i, j, u, ind
      logical :: verb
      u = output_unit (unit)
      ind = 0;  if (present (indent))  ind = indent
      verb = .true.;  if (present (verbose))  verb = verbose
```

```
      call write_indent (u, ind)
      write (u, "(1x,A)", advance="no")  "Final state:"
      do i = 1, size (object%prt)
         select type (prt_config => object%prt(i)%c)
         type is (stable_config_t)
            write (u, "(1x,A)", advance="no") &
                char (flavor_get_name (prt_config%flv(1)))
            do j = 2, size (prt_config%flv)
               write (u, "(':',A)", advance="no") &
                   char (flavor_get_name (prt_config%flv(j)))
            end do
         type is (unstable_config_t)
            write (u, "(1x,A)", advance="no") &

      end do
    end subroutine decay_term_config_compute
```

17.2.4   Decay Term

A decay term instance is selected when we generate an event for the associated
process instance. When evaluated, it triggers further decays down the chain.

Only unstable products are allocated as child particles.

⟨*Decays: types*⟩+≡
```
    type :: decay_term_t
       type(decay_term_config_t), pointer :: config => null ()
       type(particle_out_t), dimension(:), allocatable :: particle_out
     contains
     ⟨Decays: decay term: TBP⟩
    end type decay_term_t
```

Finalizer.

⟨*Decays: decay term: TBP*⟩≡
```
    procedure :: final => decay_term_final
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_term_final (object)
      class(decay_term_t), intent(inout) :: object
      integer :: i
      if (allocated (object%particle_out)) then
         do i = 1, size (object%particle_out)
```

2332

```
            call object%particle_out(i)%c%final ()
         end do
      end if
   end subroutine decay_term_final
```

Output.

⟨*Decays: decay term: TBP*⟩+≡
```
   procedure :: write => decay_term_write
```

⟨*Decays: procedures*⟩+≡
```
   recursive subroutine decay_term_write (object, unit, indent)
     class(decay_term_t), intent(in) :: object
     integer, intent(in), optional :: unit, indent
     integer :: i, u, ind
     u = output_unit (unit)
     ind = 0;  if (present (indent))  ind = indent
     call object%config%write (u, ind, verbose = .false.)
     do i = 1, size (object%particle_out)
        call object%particle_out(i)%c%write (u, ind)
     end do
   end subroutine decay_term_write
```

Recursively write the embedded process instances.

⟨*Decays: decay term: TBP*⟩+≡
```
   procedure :: write_process_instances => decay_term_write_process_instances
```

⟨*Decays: procedures*⟩+≡
```
   recursive subroutine decay_term_write_process_instances (term, unit, verbose)

            type is (stable_t)
               call stable%init (prt_config)
            end select
         type is (unstable_config_t)
            allocate (unstable_t :: term%particle_out(i)%c)
            select type (unstable => term%particle_out(i)%c)
            type is (unstable_t)
               call unstable%init (prt_config)
            end select
         end select
      end do
   end subroutine decay_term_init
```

Implement a RNG instance, spawned by the process object.

⟨*Decays: decay term: TBP*⟩+≡
```
      procedure :: make_rng => decay_term_make_rng
```

⟨*Decays: procedures*⟩+≡
```
   subroutine decay_term_make_rng (term, process)
     class(decay_term_t), intent(inout) :: term
     type(process_t), intent(inout) :: process
     class(rng_t), allocatable :: rng
     integer :: i
     do i = 1, size (term%particle_out)
        select type (unstable => term%particle_out(i)%c)
        type is (unstable_t)
           call process%make_rng (rng)
           call unstable%import_rng (rng)
        end select
     end do
   end subroutine decay_term_make_rng
```

Link the interactions for unstable decay products to the interaction of the parent process.

⟨*Decays: decay term: TBP*⟩+≡
```
      procedure :: link_interactions => decay_term_link_interactions
```

⟨*Decays: procedures*⟩+≡
```
   recursive subroutine decay_term_link_interactions (term, trace)
     class(decay_term_t), intent(inout) :: term
     type(interaction_t), intent(in), target :: trace
     integer :: i
     do i = 1, size (term%particle_out)
        select type (unstable => term%particle_out(i)%c)
        type is (unstable_t)
           call unstable%link_interactions (i, trace)
        end select
     end do
   end subroutine decay_term_link_interactions
```

Recursively generate a decay chain, for each of the unstable particles in the final state.

⟨*Decays: decay term: TBP*⟩+≡
```
    procedure :: select_chain => decay_term_select_chain
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_term_select_chain (term)
      class(decay_term_t), intent(inout) :: term
      integer :: i
      do i = 1, size (term%particle_out)
         select type (unstable => term%particle_out(i)%c)
         type is (unstable_t)
            call unstable%select_chain ()
         end select
      end do
    end subroutine decay_term_select_chain
```

Recursively generate a decay event, for each of the unstable particles in the final state.

⟨*Decays: decay term: TBP*⟩+≡
```
    procedure :: generate => decay_term_generate
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_term_generate (term)
      class(decay_term_t), intent(inout) :: term
      integer :: i
      do i = 1, size (term%particle_out)
         select type (unstable => term%particle_out(i)%c)
         type is (unstable_t)
            call unstable%generate ()
         end select
      end do
    end subroutine decay_term_generate
```

17.2.5   Decay Root Configuration

At the root of a decay chain, there is a parent process. The decay root stores a pointer to the parent process and the set of decay configurations.

⟨*Decays: types*⟩+≡
```
    type :: decay_root_config_t
      type(string_t) :: process_id
      type(process_t), pointer :: process => null ()
      type(model_t), pointer :: model => null ()
      type(decay_term_config_t), dimension(:), allocatable :: term_config
     contains
     ⟨Decays: decay root config: TBP⟩
    end type decay_root_config_t
```

The finalizer is recursive since there may be cascade decays.

⟨*Decays: decay root config: TBP*⟩≡
```
    procedure :: final => decay_root_config_final
```

2335

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_root_config_final (object)
      class(decay_root_config_t), intent(inout) :: object
      integer :: i
      if (allocated (object%term_config)) then
         do i = 1, size (object%term_config)
            call object%term_config(i)%final ()
         end do
      end if
    end subroutine decay_root_config_final
```

The output routine is also recursive, and it contains an adjustable indentation.

⟨*Decays: decay root config: TBP*⟩+≡
```
    procedure :: write => decay_root_config_write
    procedure :: write_header => decay_root_config_write_header
    procedure :: write_terms => decay_root_config_write_terms
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_root_config_write (object, unit, indent, verbose)
      class(decay_root_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
      integer :: u, ind
      u = output_unit (unit)
      ind = 0;  if (present (indent))  ind = indent
      call write_indent (u, ind)
      write (u, "(1x,A)")  "Final-state decay tree:"
      call object%write_header (unit, indent)
      call object%write_terms (unit, indent, verbose)
    end subroutine decay_root_config_write

    subroutine decay_root_config_write_header (object, unit, indent)
      class(decay_root_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      integer :: u, ind
      u = output_unit (unit)
      ind = 0;  if (present (indent))  ind = indent
      call write_indent (u, ind)
      if (associated (object%process)) then
         write (u, 3)  "process ID      =", char (object%process_id), "*"
      else
         write (u, 3)  "process ID      =", char (object%process_id)
      end if
  3   format (3x,A,2(1x,A))
    end subroutine decay_root_config_write_header

    recursive subroutine decay_root_config_write_terms &
         (object, unit, indent, verbose)
      class(decay_root_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
      integer :: i, u, ind
      logical :: verb
      u = output_unit (unit)
```

```
        ind = 0;  if (present (indent))  ind = indent
        verb = .true.;  if (present (verbose))  verb = verbose
        if (verb .and. allocated (object%term_config)) then
           do i = 1, size (object%term_config)
              call object%term_config(i)%write (u, ind + 1)
           end do
        end if
     end subroutine decay_root_config_write_terms
```

Initialize for a named process and (optionally) a pre-determined number of terms.

⟨*Decays: decay root config: TBP*⟩+≡
```
     procedure :: init => decay_root_config_init
```

⟨*Decays: procedures*⟩+≡
```
     subroutine decay_root_config_init (decay, model, process_id, n_terms)
       class(decay_root_config_t), intent(out) :: decay
       type(model_t), intent(in), target :: model
       type(string_t), intent(in) :: process_id
       integer, intent(in), optional :: n_terms
       decay%model => model
       decay%process_id = process_id
       if (present (n_terms)) then
          allocate (decay%term_config (n_terms))
       end if
     end subroutine decay_root_config_init
```

Declare a decay term, given an array of flavors.

⟨*Decays: decay root config: TBP*⟩+≡
```
     procedure :: init_term => decay_root_config_init_term
```

⟨*Decays: procedures*⟩+≡
```
     recursive subroutine decay_root_config_init_term &
          (decay, i, flv, stable, model, process_stack)
       class(decay_root_config_t), intent(inout) :: decay
       integer, intent(in) :: i
       type(flavor_t), dimension(:,:), intent(in) :: flv
       logical, dimension(:), intent(in) :: stable
       type(model_t), intent(in), target :: model
       type(process_stack_t), intent(in), optional :: process_stack
       call decay%term_config(i)%init (flv, stable, model, process_stack)
     end subroutine decay_root_config_init_term
```

Connect the decay root configuration with a process object (which should represent the parent process). This includes initialization, therefore intent(out).

The flavor state is retrieved from the process term object. However, we have to be careful: the flavor object points to the model instance that is stored in the process object. This model instance may not contain the current setting for unstable particles and decay. Therefore, we assign the model directly.

If the `process_instance` argument is provided, we use this for the flavor state. This applies to the decay root only, where the process can be entangled with a beam setup, and the latter contains beam remnants as further outgoing

particles. These must be included in the set of outgoing flavors, since the decay application is also done on the connected state.

Infer stability from the particle properties, using the first row in the set of flavor states. For unstable particles, we look for decays, recursively, available from the process stack (if present).

⟨*Decays: decay root config: TBP*⟩+≡
```
    procedure :: connect => decay_root_config_connect
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_root_config_connect &
         (decay, process, model, process_stack, process_instance)
      class(decay_root_config_t), intent(out) :: decay
      type(process_t), intent(in), target :: process
      type(model_t), intent(in), target :: model
      type(process_stack_t), intent(in), optional :: process_stack
      type(process_instance_t), intent(in), optional, target :: process_instance
      type(connected_state_t), pointer :: connected_state
      type(interaction_t), pointer :: int
      type(flavor_t), dimension(:,:), allocatable :: flv
      logical, dimension(:), allocatable :: stable
      integer :: i
      call decay%init (model, process%get_id (), process%get_n_terms ())
      do i = 1, size (decay%term_config)
         if (present (process_instance)) then
            connected_state => process_instance%get_connected_state_ptr (i)
            int => connected_state%get_matrix_int_ptr ()
            call interaction_get_flv_out (int, flv)
         else
            call process%get_term_flv_out (i, flv)
         end if
         call flavor_set_model (flv, model)
         allocate (stable (size (flv, 1)))
         stable = flavor_is_stable (flv(:,1))
         call decay%init_term (i, flv, stable, model, process_stack)
         deallocate (flv, stable)
      end do
      decay%process => process
    end subroutine decay_root_config_connect
```

Recursively compute widths, errors, and branching ratios.

⟨*Decays: decay root config: TBP*⟩+≡
```
    procedure :: compute => decay_root_config_compute
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_root_config_compute (decay)
      class(decay_root_config_t), intent(inout) :: decay
      integer :: i
      do i = 1, size (decay%term_config)
         call decay%term_config(i)%compute ()
      end do
    end subroutine decay_root_config_compute
```

17.2.6 Decay Root Instance

This is the common parent type for decay and decay root. The process instance points to the parent process. The model pointer is separate because particle settings may be updated w.r.t. the parent process object.

⟨*Decays: types*⟩+≡
```
type, abstract :: decay_gen_t
  type(decay_term_t), dimension(:), allocatable :: term
  type(process_instance_t), pointer :: process_instance => null ()
  integer :: selected_mci = 0
  integer :: selected_term = 0
 contains
 ⟨Decays: decay gen: TBP⟩
end type decay_gen_t
```

The decay root represents the parent process. When an event is generated, the generator selects the term to which the decay chain applies (if possible).

The process instance is just a pointer.

⟨*Decays: types*⟩+≡
```
type, extends (decay_gen_t) :: decay_root_t
  type(decay_root_config_t), pointer :: config => null ()
 contains
 ⟨Decays: decay root: TBP⟩
end type decay_root_t
```

The finalizer has to recursively finalize the terms, but we can skip the process instance which is not explicitly allocated.

⟨*Decays: decay gen: TBP*⟩≡
```
procedure :: base_final => decay_gen_final
```

⟨*Decays: procedures*⟩+≡
```
recursive subroutine decay_gen_final (object)
  class(decay_gen_t), intent(inout) :: object
  integer :: i
  if (allocated (object%term)) then
     do i = 1, size (object%term)
        call object%term(i)%final ()
     end do
  end if
end subroutine decay_gen_final
```

No extra finalization for the decay root.

⟨*Decays: decay root: TBP*⟩≡
```
procedure :: final => decay_root_final
```

⟨*Decays: procedures*⟩+≡
```
subroutine decay_root_final (object)
  class(decay_root_t), intent(inout) :: object
  call object%base_final ()
end subroutine decay_root_final
```

Output.

⟨*Decays: decay root: TBP*⟩+≡
```
    procedure :: write => decay_root_write
```

⟨*Decays: procedures*⟩+≡
```
    subroutine decay_root_write (object, unit)
      class(decay_root_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u
      u = output_unit (unit)
      if (associated (object%config)) then
         call object%config%write (unit, verbose = .false.)
      else
         write (u, "(1x,A)")  "Final-state decay tree: [not configured]"
      end if
      if (object%selected_mci > 0) then
         write (u, "(3x,A,I0)")  "Selected MCI    = ", object%selected_mci
      else
         write (u, "(3x,A)")  "Selected MCI    = [undefined]"
      end if
      if (object%selected_term > 0) then
         write (u, "(3x,A,I0)")  "Selected term   = ", object%selected_term
         call object%term(object%selected_term)%write (u, 1)
      else
         write (u, "(3x,A)")  "Selected term   = [undefined]"
      end if
    end subroutine decay_root_write
```

Write the process instances, recursively.

⟨*Decays: decay gen: TBP*⟩+≡
```
    procedure :: write_process_instances => decay_gen_write_process_instances
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_gen_write_process_instances (decay, unit, verbose)
      class(decay_gen_t), intent(in) :: decay
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: verbose
      logical :: verb
      verb = .true.;  if (present (verbose))  verb = verbose
      if (associated (decay%process_instance)) then
         if (verb) then
            call decay%process_instance%write (unit)
         else
            call decay%process_instance%write_header (unit)
         end if
      end if
      if (decay%selected_term > 0) then
         call decay%term(decay%selected_term)%write_process_instances (unit, verb)
      end if
    end subroutine decay_gen_write_process_instances
```

Generic initializer. All can be done recursively.

⟨*Decays: decay gen: TBP*⟩+≡
```
    procedure :: base_init => decay_gen_init
```

⟨*Decays: procedures*⟩+≡

```
    recursive subroutine decay_gen_init (decay, term_config)
      class(decay_gen_t), intent(out) :: decay
      type(decay_term_config_t), dimension(:), intent(in), target :: term_config
      integer :: i
      allocate (decay%term (size (term_config)))
      do i = 1, size (decay%term)
         call decay%term(i)%init (term_config(i))
      end do
    end subroutine decay_gen_init
```

Specific initializer. We assign the configuration object, which should correspond
to a completely initialized decay configuration tree. We also connect to an
existing process instance. Then, we recursively link the child interactions to the
parent process.

⟨*Decays: decay root: TBP*⟩+≡

```
    procedure :: init => decay_root_init
```

⟨*Decays: procedures*⟩+≡

```
    subroutine decay_root_init (decay_root, config, process_instance)
      class(decay_root_t), intent(out) :: decay_root
      type(decay_root_config_t), intent(in), target :: config
      type(process_instance_t), intent(in), target :: process_instance
      call decay_root%base_init (config%term_config)
      decay_root%config => config
      decay_root%process_instance => process_instance
      call decay_root%make_term_rng (config%process)
      call decay_root%link_term_interactions ()
    end subroutine decay_root_init
```

Implement random-number generators for unstable decay selection in all terms.
This is not recursive.

   We also make use of the fact that `process` is a pointer; the (state of the
RNG factory inside the) target process will be modified by the rng-spawning
method, but not the pointer.

⟨*Decays: decay gen: TBP*⟩+≡

```
    procedure :: make_term_rng => decay_gen_make_term_rng
```

⟨*Decays: procedures*⟩+≡

```
    subroutine decay_gen_make_term_rng (decay, process)
      class(decay_gen_t), intent(inout) :: decay
      type(process_t), intent(in), pointer :: process
      integer :: i
      do i = 1, size (decay%term)
         call decay%term(i)%make_rng (process)
      end do
    end subroutine decay_gen_make_term_rng
```

Recursively link interactions of the enclosed decay terms to the corresponding
terms in the current process instance.

   Note: A bug in nagfor requires the extra `i_term` variable.

⟨*Decays: decay gen: TBP*⟩+≡

```
    procedure :: link_term_interactions => decay_gen_link_term_interactions
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_gen_link_term_interactions (decay)
      class(decay_gen_t), intent(inout) :: decay
      integer :: i, i_term
      type(interaction_t), pointer :: trace
      associate (instance => decay%process_instance)
        do i = 1, size (decay%term)
           i_term = i
           trace => instance%get_trace_int_ptr (i_term)
           call decay%term(i_term)%link_interactions (trace)
        end do
      end associate
    end subroutine decay_gen_link_term_interactions
```

Select a decay chain: decay modes and process components.

⟨*Decays: decay root: TBP*⟩+≡
```
    procedure :: select_chain => decay_root_select_chain
```

⟨*Decays: procedures*⟩+≡
```
    subroutine decay_root_select_chain (decay_root)
      class(decay_root_t), intent(inout) :: decay_root
      if (decay_root%selected_term > 0) then
         call decay_root%term(decay_root%selected_term)%select_chain ()
      else
         call msg_bug ("Decays: no term selected for parent process")
      end if
    end subroutine decay_root_select_chain
```

Generate a decay tree, i.e., for the selected term in the parent process, recursively generate a decay event for all unstable particles.

Factor out the trace of the connected state of the parent process. This trace should not be taken into account for unweighting the decay chain, since it was already used for unweighting the parent event, or it determines the overall event weight.

⟨*Decays: decay root: TBP*⟩+≡
```
    procedure :: generate => decay_root_generate
```

⟨*Decays: procedures*⟩+≡
```
    subroutine decay_root_generate (decay_root)
      class(decay_root_t), intent(inout) :: decay_root
      type(connected_state_t), pointer :: connected_state
      if (decay_root%selected_term > 0) then
         connected_state => decay_root%process_instance%get_connected_state_ptr &
              (decay_root%selected_term)
         call connected_state%normalize_matrix_by_trace ()
         call decay_root%term(decay_root%selected_term)%generate ()
      else
         call msg_bug ("Decays: no term selected for parent process")
      end if
    end subroutine decay_root_generate
```

17.2.7 Decay Configuration

A decay configuration describes a distinct decay mode of a particle. Each decay mode may include several terms, which correspond to the terms in the associated process. In addition to the base type, the decay configuration object contains the integral of the parent process and the selector for the MCI group inside this process.

⟨*Decays: types*⟩+≡
```
type, extends (decay_root_config_t) :: decay_config_t
  real(default) :: weight = 0
  real(default) :: integral = 0
  real(default) :: abs_error = 0
  real(default) :: rel_error = 0
  type(selector_t) :: mci_selector
 contains
 ⟨Decays: decay config: TBP⟩
 end type decay_config_t
```

The output routine extends the decay-root writer by listing numerical component values.

⟨*Decays: decay config: TBP*⟩≡
```
procedure :: write => decay_config_write
```

⟨*Decays: procedures*⟩+≡
```
recursive subroutine decay_config_write (object, unit, indent, verbose)
  class(decay_config_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent
  logical, intent(in), optional :: verbose
  integer :: u, ind
  u = output_unit (unit)
  ind = 0;  if (present (indent))  ind = indent
  call write_indent (u, ind)
  write (u, "(1x,A)")  "Decay:"
  call object%write_header (unit, indent)
  call write_indent (u, ind)
  write (u, 2)  "branching ratio =", object%weight * 100
  call write_indent (u, ind)
  write (u, 1)  "partial width   =", object%integral
  call write_indent (u, ind)
  write (u, 1)  "error (abs)     =", object%abs_error
  call write_indent (u, ind)
  write (u, 1)  "error (rel)     =", object%rel_error
1   format (3x,A,ES19.12)
2   format (3x,A,F11.6,1x,'%')
  call object%write_terms (unit, indent, verbose)
 end subroutine decay_config_write
```

Connect a decay configuration with a process object (which should represent the decay). This includes initialization, therefore intent(out). We first connect the process itself, then do initializations that are specific for this decay.

Infer stability from the particle properties, using the first row in the set of flavor states. Once we can deal with predetermined decay chains, they should

be used instead.

⟨*Decays: decay config: TBP*⟩+≡
```
    procedure :: connect => decay_config_connect
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_config_connect &
         (decay, process, model, process_stack, process_instance)
      class(decay_config_t), intent(out) :: decay
      type(process_t), intent(in), target :: process
      type(model_t), intent(in), target :: model
      type(process_stack_t), intent(in), optional :: process_stack
      type(process_instance_t), intent(in), optional, target :: process_instance
      real(default), dimension(:), allocatable :: integral_mci
      integer :: i, n_mci
      call decay%decay_root_config_t%connect (process, model, process_stack)
      decay%integral = process%get_integral ()
      decay%abs_error = process%get_error ()
      if (process%cm_frame ()) then
         call msg_fatal ("Decay process " // char (process%get_id ()) &
              // ": unusable because rest frame is fixed.")
      end if
      n_mci = process%get_n_mci ()
      allocate (integral_mci (n_mci))
      do i = 1, n_mci
         integral_mci(i) = process%get_integral_mci (i)
      end do
      call decay%mci_selector%init (integral_mci)
    end subroutine decay_config_connect
```

Compute embedded branchings and the relative error. This method does not
apply to the decay root.

⟨*Decays: decay config: TBP*⟩+≡
```
    procedure :: compute => decay_config_compute
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_config_compute (decay)
      class(decay_config_t), intent(inout) :: decay
      call decay%decay_root_config_t%compute ()
      if (decay%integral == 0) then
         call decay%write ()
         call msg_fatal ("Decay configuration: partial width is zero")
      end if
      decay%rel_error = decay%abs_error / decay%integral
    end subroutine decay_config_compute
```

17.2.8 Decay Instance

The decay contains a collection of terms. One of them is selected when the
decay is evaluated. This is similar to the decay root, but we implement it
independently.

The process instance object is allocated via a pointer, so it automatically
behaves as a target.

⟨*Decays: types*⟩+≡

```
    type, extends (decay_gen_t) :: decay_t
      type(decay_config_t), pointer :: config => null ()
      class(rng_t), allocatable :: rng
     contains
     ⟨Decays: decay: TBP⟩
    end type decay_t
```

The finalizer is recursive.

⟨*Decays: decay: TBP*⟩≡
```
    procedure :: final => decay_final
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_final (object)
      class(decay_t), intent(inout) :: object
      integer :: i
      call object%base_final ()
      do i = 1, object%config%process%get_n_mci ()
         call object%process_instance%final_simulation (i)
      end do
      call object%process_instance%final ()
      deallocate (object%process_instance)
    end subroutine decay_final
```

Output.

⟨*Decays: decay: TBP*⟩+≡
```
    procedure :: write => decay_write
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_write (object, unit, indent, recursive)
      class(decay_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent, recursive
      integer :: u, ind
      u = output_unit (unit)
      ind = 0;  if (present (indent))  ind = indent
      call object%config%write (unit, indent, verbose = .false.)
      if (allocated (object%rng)) then
         call object%rng%write (u, ind + 1)
      end if
      call write_indent (u, ind)
      if (object%selected_mci > 0) then
         write (u, "(3x,A,I0)")  "Selected MCI   = ", object%selected_mci
      else
         write (u, "(3x,A)")  "Selected MCI   = [undefined]"
      end if
      call write_indent (u, ind)
      if (object%selected_term > 0) then
         write (u, "(3x,A,I0)")  "Selected term  = ", object%selected_term
         call object%term(object%selected_term)%write (u, ind + 1)
      else
         write (u, "(3x,A)")  "Selected term  = [undefined]"
      end if
    end subroutine decay_write
```

Initializer. Base initialization is done recursively. Then, we prepare the current process instance and allocate a random-number generator for term selection. For all unstable particles, we also allocate a r.n.g. as spawned by the current process.

⟨*Decays: decay: TBP*⟩+≡
```
    procedure :: init => decay_init
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_init (decay, config)
      class(decay_t), intent(out) :: decay
      type(decay_config_t), intent(in), target :: config
      integer :: i
      call decay%base_init (config%term_config)
      decay%config => config
      allocate (decay%process_instance)
      call decay%process_instance%init (decay%config%process)
      call decay%process_instance%setup_event_data (decay%config%model)
      do i = 1, decay%config%process%get_n_mci ()
         call decay%process_instance%init_simulation (i)
      end do
      call decay%config%process%make_rng (decay%rng)
      call decay%make_term_rng (decay%config%process)
    end subroutine decay_init
```

Link interactions to the parent process. `i_prt` is the index of the current outgoing particle in the parent interaction, for which we take the trace evaluator. We link it to the beam particle in the beam interaction of the decay process instance. Then, repeat the procedure for the outgoing particles.

⟨*Decays: decay: TBP*⟩+≡
```
    procedure :: link_interactions => decay_link_interactions
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_link_interactions (decay, i_prt, trace)
      class(decay_t), intent(inout) :: decay
      integer, intent(in) :: i_prt
      type(interaction_t), intent(in), target :: trace
      type(interaction_t), pointer :: beam_int
      integer :: n_in, n_vir
      beam_int => decay%process_instance%get_beam_int_ptr ()
      n_in = interaction_get_n_in (trace)
      n_vir = interaction_get_n_vir (trace)
      call interaction_set_source_link (beam_int, 1, trace, &
           n_in + n_vir + i_prt)
      call decay%link_term_interactions ()
    end subroutine decay_link_interactions
```

Determine a decay chain. For each unstable particle we select one of the possible decay modes, and for each decay process we select one of the possible decay MCI components, calling the random-number generators. We do not generate momenta, yet.

⟨*Decays: decay: TBP*⟩+≡
```
    procedure :: select_chain => decay_select_chain
```

⟨*Decays: procedures*⟩+≡
```
recursive subroutine decay_select_chain (decay)
  class(decay_t), intent(inout) :: decay
  real(default) :: x
  integer :: i
  call decay%rng%generate (x)
  decay%selected_mci = decay%config%mci_selector%select (x)
  call decay%process_instance%choose_mci (decay%selected_mci)
  call decay%process_instance%select_i_term (decay%selected_term)
  do i = 1, size (decay%term)
     call decay%term(i)%select_chain ()
  end do
end subroutine decay_select_chain
```

Generate a decay. We first receive the beam momenta from the parent process (assuming that this is properly linked), then call the associated process object for a new event.

Factor out the trace of the helicity density matrix of the isolated state (the one that will be used for the decay chain). The trace is taken into account for unweighting the individual decay event and should therefore be ignored for unweighting the correlated decay chain afterwards.

⟨*Decays: decay: TBP*⟩+≡
```
procedure :: generate => decay_generate
```

⟨*Decays: procedures*⟩+≡
```
recursive subroutine decay_generate (decay)
  class(decay_t), intent(inout) :: decay
  type(isolated_state_t), pointer :: isolated_state
  integer :: i
  call decay%process_instance%receive_beam_momenta ()
  call decay%config%process%generate_unweighted_event &
       (decay%process_instance, decay%selected_mci)
  if (signal_is_pending ())  return
  call decay%process_instance%evaluate_event_data ()
  isolated_state => &
       decay%process_instance%get_isolated_state_ptr (decay%selected_term)
  call isolated_state%normalize_matrix_by_trace ()
  do i = 1, size (decay%term)
     call decay%term(i)%generate ()
     if (signal_is_pending ())  return
  end do
end subroutine decay_generate
```

17.2.9   Stable Particles

This is a stable particle. The flavor can be ambiguous (e.g., partons).

⟨*Decays: types*⟩+≡
```
type, extends (any_config_t) :: stable_config_t
  type(flavor_t), dimension(:), allocatable :: flv
 contains
  ⟨Decays: stable config: TBP⟩
```

```
      end type stable_config_t
```

The finalizer is empty:

⟨Decays: stable config: TBP⟩≡
```
    procedure :: final => stable_config_final
```

⟨Decays: procedures⟩+≡
```
    subroutine stable_config_final (object)
      class(stable_config_t), intent(inout) :: object
    end subroutine stable_config_final
```

Output.

⟨Decays: stable config: TBP⟩+≡
```
    procedure :: write => stable_config_write
```

⟨Decays: procedures⟩+≡
```
    recursive subroutine stable_config_write (object, unit, indent, verbose)
      class(stable_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
      integer :: u, i, ind
      u = output_unit (unit)
      ind = 0;  if (present (indent))  ind = indent
      call write_indent (u, ind)
      write (u, "(1x,'+',1x,A)", advance = "no")  "Stable:"
      write (u, "(1x,A)", advance = "no")  char (flavor_get_name (object%flv(1)))
      do i = 2, size (object%flv)
         write (u, "(':',A)", advance = "no") &
              char (flavor_get_name (object%flv(i)))
      end do
      write (u, *)
    end subroutine stable_config_write
```

Initializer. We are presented with an array of flavors, but there may be double
entries which we remove, so we store only the distinct flavors.

⟨Decays: stable config: TBP⟩+≡
```
    procedure :: init => stable_config_init
```

⟨Decays: procedures⟩+≡
```
    subroutine stable_config_init (config, flv)
      class(stable_config_t), intent(out) :: config
      type(flavor_t), dimension(:), intent(in) :: flv
      integer, dimension (size (flv)) :: pdg
      logical, dimension (size (flv)) :: mask
      integer :: i
      pdg = flavor_get_pdg (flv)
      mask(1) = .true.
      forall (i = 2 : size (pdg))
         mask(i) = all (pdg(i) /= pdg(1:i-1))
      end forall
      allocate (config%flv (count (mask)))
      config%flv = pack (flv, mask)
    end subroutine stable_config_init
```

Here is the corresponding object instance. Except for the pointer to the configuration, there is no content.

⟨*Decays: types*⟩+≡
```
type, extends (any_t) :: stable_t
  type(stable_config_t), pointer :: config => null ()
 contains
 ⟨Decays: stable: TBP⟩
end type stable_t
```

The finalizer does nothing.

⟨*Decays: stable: TBP*⟩≡
```
procedure :: final => stable_final
```

⟨*Decays: procedures*⟩+≡
```
subroutine stable_final (object)
  class(stable_t), intent(inout) :: object
end subroutine stable_final
```

We can delegate output to the configuration object.

⟨*Decays: stable: TBP*⟩+≡
```
procedure :: write => stable_write
```

⟨*Decays: procedures*⟩+≡
```
subroutine stable_write (object, unit, indent)
  class(stable_t), intent(in) :: object
  integer, intent(in), optional :: unit, indent
  call object%config%write (unit, indent)
end subroutine stable_write
```

Initializer: just assign the configuration.

⟨*Decays: stable: TBP*⟩+≡
```
procedure :: init => stable_init
```

⟨*Decays: procedures*⟩+≡
```
subroutine stable_init (stable, config)
  class(stable_t), intent(out) :: stable
  type(stable_config_t), intent(in), target :: config
  stable%config => config
end subroutine stable_init
```

17.2.10 Unstable Particles

A branching configuration enables us to select among distinct decay modes of a particle. We store the particle flavor (with its implicit link to a model), an array of decay configurations, and a selector object.

The total width, absolute and relative error are stored as `integral`, `abs_error`, and `rel_error`, respectively.

The flavor must be unique in this case.

⟨*Decays: types*⟩+≡
```
type, extends (any_config_t) :: unstable_config_t
  type(flavor_t) :: flv
```

```
      real(default) :: integral = 0
      real(default) :: abs_error = 0
      real(default) :: rel_error = 0
      type(selector_t) :: selector
      type(decay_config_t), dimension(:), allocatable :: decay_config
    contains
    ⟨Decays: unstable config: TBP⟩
    end type unstable_config_t
```

Finalizer. The branching configuration can be a recursive structure.

⟨*Decays: unstable config: TBP*⟩≡
```
    procedure :: final => unstable_config_final
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine unstable_config_final (object)
      class(unstable_config_t), intent(inout) :: object
      integer :: i
      if (allocated (object%decay_config)) then
         do i = 1, size (object%decay_config)
            call object%decay_config(i)%final ()
         end do
      end if
    end subroutine unstable_config_final
```

Output. Since this may be recursive, we include indentation.

⟨*Decays: unstable config: TBP*⟩+≡
```
    procedure :: write => unstable_config_write
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine unstable_config_write (object, unit, indent, verbose)
      class(unstable_config_t), intent(in) :: object
      integer, intent(in), optional :: unit, indent
      logical, intent(in), optional :: verbose
      integer :: u, i, ind
      logical :: verb
      u = output_unit (unit)
      ind = 0;  if (present (indent))  ind = indent
      verb = .true.;  if (present (verbose))  verb = verbose
      call write_indent (u, ind)
      write (u, "(1x,'+',1x,A,1x,A)")  "Unstable:", &
           char (flavor_get_name (object%flv))
      call write_indent (u, ind)
      write (u, 1)  "total width =", object%integral
      call write_indent (u, ind)
      write (u, 1)  "error (abs) =", object%abs_error
      call write_indent (u, ind)
      write (u, 1)  "error (rel) =", object%rel_error
  1   format (5x,A,ES19.12)
      if (verb .and. allocated (object%decay_config)) then
         do i = 1, size (object%decay_config)
            call object%decay_config(i)%write (u, ind + 1)
         end do
      end if
    end subroutine unstable_config_write
```

2350

Initializer. For the unstable particle, the flavor is unique.

⟨*Decays: unstable config: TBP*⟩+≡
```
    procedure :: init => unstable_config_init
```

⟨*Decays: procedures*⟩+≡
```
    subroutine unstable_config_init (config, flv)
      class(unstable_config_t), intent(out) :: config
      type(flavor_t), intent(in) :: flv
      config%flv = flv
    end subroutine unstable_config_init
```

Further initialization: determine the number of decay modes. We can assume that the flavor of the particle has been set already.

If the process stack is given, we can delve recursively into actually assigning decay processes. Otherwise, we just initialize with decay process names.

⟨*Decays: unstable config: TBP*⟩+≡
```
    procedure :: init_decays => unstable_config_init_decays
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine unstable_config_init_decays &
        (unstable, decay_id, model, process_stack)
      class(unstable_config_t), intent(inout) :: unstable
      type(string_t), dimension(:), intent(in) :: decay_id
      type(model_t), intent(in), target :: model
      type(process_stack_t), intent(in), optional :: process_stack
      integer :: i
      allocate (unstable%decay_config (size (decay_id)))
      do i = 1, size (decay_id)
         associate (decay => unstable%decay_config(i))
           if (present (process_stack)) then
              call decay%connect (process_stack%get_process_ptr (decay_id(i)), &
                   model, process_stack)
           else
              call decay%init (model, decay_id(i))
           end if
         end associate
      end do
    end subroutine unstable_config_init_decays
```

Compute the total width and branching ratios, initializing the decay selector.

⟨*Decays: unstable config: TBP*⟩+≡
```
    procedure :: compute => unstable_config_compute
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine unstable_config_compute (unstable)
      class(unstable_config_t), intent(inout) :: unstable
      integer :: i
      do i = 1, size (unstable%decay_config)
         call unstable%decay_config(i)%compute ()
      end do
      unstable%integral = sum (unstable%decay_config%integral)
      if (unstable%integral <= 0) then
```

```
            call unstable%write ()
            call msg_fatal ("Decay configuration: computed total width is zero")
         end if
         unstable%abs_error = sqrt (sum (unstable%decay_config%abs_error ** 2))
         unstable%rel_error = unstable%abs_error / unstable%integral
         call unstable%selector%init (unstable%decay_config%integral)
         do i = 1, size (unstable%decay_config)
            unstable%decay_config(i)%weight &
                 = unstable%selector%get_weight (i)
         end do
    end subroutine unstable_config_compute
```

Now we define the instance of an unstable particle.

⟨*Decays: types*⟩+≡
```
    type, extends (any_t) :: unstable_t
       type(unstable_config_t), pointer :: config => null ()
       class(rng_t), allocatable :: rng
       integer :: selected_decay = 0
       type(decay_t), dimension(:), allocatable :: decay
     contains
     ⟨Decays: unstable: TBP⟩
    end type unstable_t
```

Recursive finalizer.

⟨*Decays: unstable: TBP*⟩≡
```
    procedure :: final => unstable_final
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine unstable_final (object)
      class(unstable_t), intent(inout) :: object
      integer :: i
      if (allocated (object%decay)) then
         do i = 1, size (object%decay)
            call object%decay(i)%final ()
         end do
      end if
    end subroutine unstable_final
```

Output.

⟨*Decays: unstable: TBP*⟩+≡
```

     integer :: i
     unstable%config => config
     allocate (unstable%decay (size (config%decay_config)))
     do i = 1, size (config%decay_config)
        call unstable%decay(i)%init (config%decay_config(i))
     end do
   end subroutine unstable_init
```

Recursively link interactions to the parent process. `i_prt` is the index of the
current outgoing particle in the parent interaction.

⟨*Decays: unstable: TBP*⟩+≡
```
   procedure :: link_interactions => unstable_link_interactions
```

⟨*Decays: procedures*⟩+≡
```
   recursive subroutine unstable_link_interactions (unstable, i_prt, trace)
     class(unstable_t), intent(inout) :: unstable
     integer, intent(in) :: i_prt
     type(interaction_t), intent(in), target :: trace
     integer :: i
     do i = 1, size (unstable%decay)
```

```
        call unstable%decay(i)%link_interactions (i_prt, trace)
      end do
    end subroutine unstable_link_interactions
```

Import the random-number generator state.

⟨*Decays: unstable: TBP*⟩+≡
```
    procedure :: import_rng => unstable_import_rng
```

⟨*Decays: procedures*⟩+≡
```
    subroutine unstable_import_rng (unstable, rng)
      class(unstable_t), intent(inout) :: unstable
      class(rng_t), intent(inout), allocatable :: rng
      call move_alloc (from = rng, to = unstable%rng)
    end subroutine unstable_import_rng
```

Generate a decay chain. First select a decay mode, then call the `select_chain` method of the selected mode.

⟨*Decays: unstable: TBP*⟩+≡
```
    procedure :: select_chain => unstable_select_chain
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine unstable_select_chain (unstable)
      class(unstable_t), intent(inout) :: unstable
      real(default) :: x
      call unstable%rng%generate (x)
      unstable%selected_decay = unstable%config%selector%select (x)
      call unstable%decay(unstable%selected_decay)%select_chain ()
    end subroutine unstable_select_chain
```

Generate a decay event.

⟨*Decays: unstable: TBP*⟩+≡
```
    procedure :: generate => unstable_generate
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine unstable_generate (unstable)
      class(unstable_t), intent(inout) :: unstable
      call unstable%decay(unstable%selected_decay)%generate ()
    end subroutine unstable_generate
```

17.2.11   Decay Chain

While the decay configuration tree and the decay tree are static entities (during a simulation run), the decay chain is dynamically generated for each event. The reason is that with the possibility of several decay modes for each particle, and several terms for each process, the total number of distinct decay chains is not under control.

Each entry in the decay chain is a connected parton state. The origin of the chain is a connected state in the parent process (not part of the chain itself). For each decay, mode and term chosen, we convolute this with the isolated (!) state of the current decay, to generate a new connected state. We accumulate this chain by recursively traversing the allocated decay tree. Whenever a particle

decays, it becomes virtual and is replaced by its decay product, while all other particles stay in the parton state as spectators.

Technically, we implement the decay chain as a stack structure and include information from the associated decay object for easier debugging. This is a decay chain entry:

⟨*Decays: types*⟩+≡
```
type, extends (connected_state_t) :: decay_chain_entry_t
  integer :: index = 0
  type(decay_config_t), pointer :: config => null ()
  integer :: selected_mci = 0
  integer :: selected_term = 0
  type(decay_chain_entry_t), pointer :: previous => null ()
end type decay_chain_entry_t
```

This is the complete chain; we need just a pointer to the last entry. We also include a pointer to the master process instance, which serves as the seed for the decay chain.

The evaluator `correlated_trace` traces over all quantum numbers for the final spin-correlated (but color-summed) evaluator of the decay chain. This allows us to compute the probability for a momentum configuration, given that all individual density matrices (of the initial process and the subsequent decays) have been normalized to one.

Note: This trace is summed over color, so color is treated exactly when computing spin correlations. However, we do not keep non-diagonal color correlations. When an event is accepted, we compute probabilities for all color states and can choose one of them.

⟨*Decays: types*⟩+≡
```
type :: decay_chain_t
  type(process_instance_t), pointer :: process_instance => null ()
  integer :: selected_term = 0
  type(evaluator_t) :: correlated_trace
  type(decay_chain_entry_t), pointer :: last => null ()
contains
⟨Decays: decay chain: TBP⟩
end type decay_chain_t
```

The finalizer recursively deletes and deallocates the entries.

⟨*Decays: decay chain: TBP*⟩≡
```
procedure :: final => decay_chain_final
```

⟨*Decays: procedures*⟩+≡
```
subroutine decay_chain_final (object)
  class(decay_chain_t), intent(inout) :: object
  type(decay_chain_entry_t), pointer :: entry
  do while (associated (object%last))
    entry => object%last
    object%last => entry%previous
    call entry%final ()
    deallocate (entry)
  end do
  call evaluator_final (object%correlated_trace)
end subroutine decay_chain_final
```

Doing output recursively allows us to display the chain in chronological order.

⟨*Decays: decay chain: TBP*⟩+≡
```
    procedure :: write => decay_chain_write
```

⟨*Decays: procedures*⟩+≡
```
    subroutine decay_chain_write (object, unit)
      class(decay_chain_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u
      u = output_unit (unit)
      call write_separator_double (u)
      write (u, "(1x,A)")  "Decay chain:"
      call write_entries (object%last)
      call write_separator_double (u)
      write (u, "(1x,A)")  "Evaluator (correlated trace of the decay chain):"
      call write_separator (u)
      call object%correlated_trace%write (u)
      call write_separator_double (u)
    contains
      recursive subroutine write_entries (entry)
        type(decay_chain_entry_t), intent(in), pointer :: entry
        if (associated (entry)) then
           call write_entries (entry%previous)
           call write_separator_double (u)
           write (u, "(1x,A,I0)")  "Decay #", entry%index
           call entry%config%write_header (u)
           write (u, "(3x,A,I0)")  "Selected MCI   = ", entry%selected_mci
           write (u, "(3x,A,I0)")  "Selected term  = ", entry%selected_term
           call entry%config%term_config(entry%selected_term)%write (u, indent=1)
           call entry%write (u)
        end if
      end subroutine write_entries
    end subroutine decay_chain_write
```

Build a decay chain, recursively following the selected decays and terms in a decay tree. Before start, we finalize the chain, deleting any previous contents.

⟨*Decays: decay chain: TBP*⟩+≡
```
    procedure :: build => decay_chain_build
```

⟨*Decays: procedures*⟩+≡
```
    subroutine decay_chain_build (chain, decay_root)
      class(decay_chain_t), intent(inout), target :: chain
      type(decay_root_t), intent(in) :: decay_root
      type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
      type(interaction_t), pointer :: int_last_decay
      call chain%final ()
      if (decay_root%selected_term > 0) then
         chain%process_instance => decay_root%process_instance
         chain%selected_term = decay_root%selected_term
         call chain%build_term_entries (decay_root%term(decay_root%selected_term))
      end if
      int_last_decay => chain%last%get_matrix_int_ptr ()
      allocate (qn_mask (interaction_get_n_tot (int_last_decay)))
```

```
      call quantum_numbers_mask_init (qn_mask, &
          mask_f = .true., mask_c = .true., mask_h = .true.)
      call evaluator_init_qn_sum (chain%correlated_trace, int_last_decay, qn_mask)
    end subroutine decay_chain_build
```

Build the entries that correspond to a decay term. We have to scan all unstable
particles.

⟨*Decays: decay chain: TBP*⟩+≡
```
    procedure :: build_term_entries => decay_chain_build_term_entries
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_chain_build_term_entries (chain, term)
      class(decay_chain_t), intent(inout) :: chain
      type(decay_term_t), intent(in) :: term
      integer :: i
      do i = 1, size (term%particle_out)
         select type (unstable => term%particle_out(i)%c)
         type is (unstable_t)
            if (unstable%selected_decay > 0) then
               call chain%build_decay_entries &
                    (unstable%decay(unstable%selected_decay))
            end if
         end select
      end do
    end subroutine decay_chain_build_term_entries
```

Build the entries that correspond to a specific decay. The decay term should
have been determined, so we allocate a decay chain entry and fill it, then proceed
to child decays.

For the first entry, we convolute the connected state of the parent process
instance with the isolated state of the current decay (which does not contain an
extra beam entry for the parent). For subsequent entries, we take the previous
entry as first factor.

In principle, each chain entry (as a parton state) is capable of holding a
subevent object and associated expressions. We currently do not make use of
that feature.

Before generating the decays, factor out the trace of the helicity density
matrix of the parent parton state. This trace has been used for unweighting the
original event (unweighted case) or it determines the overall weight, so it should
not be taken into account in the decay chain generation.

⟨*Decays: decay chain: TBP*⟩+≡
```
    procedure :: build_decay_entries => decay_chain_build_decay_entries
```

⟨*Decays: procedures*⟩+≡
```
    recursive subroutine decay_chain_build_decay_entries (chain, decay)
      class(decay_chain_t), intent(inout) :: chain
      type(decay_t), intent(in) :: decay
      type(decay_chain_entry_t), pointer :: entry
      type(connected_state_t), pointer :: previous_state
      type(isolated_state_t), pointer :: current_decay
      allocate (entry)
      if (associated (chain%last)) then
```

```
        entry%previous => chain%last
        entry%index = entry%previous%index + 1
        previous_state => entry%previous%connected_state_t
    else
        entry%index = 1
        previous_state => &
            chain%process_instance%get_connected_state_ptr (chain%selected_term)
    end if
    entry%config => decay%config
    entry%selected_mci = decay%selected_mci
    entry%selected_term = decay%selected_term
    current_decay => decay%process_instance%get_isolated_state_ptr &
        (decay%selected_term)
    call entry%setup_connected_trace &
        (current_decay, previous_state%get_trace_int_ptr ())
    call entry%setup_connected_matrix &
        (current_decay, previous_state%get_matrix_int_ptr ())
    call entry%setup_connected_flows &
        (current_decay, previous_state%get_flows_int_ptr ())
    chain%last => entry
    call chain%build_term_entries (decay%term(decay%selected_term))
  end subroutine decay_chain_build_decay_entries
```

Recursively fill the decay chain with momenta and evaluate the matrix elements. Since all evaluators should have correct source entries at this point, momenta are automatically retrieved from the appropriate process instance.

Like we did above for the parent process, factor out the trace for each subsequent decay (the helicity density matrix in the isolated state, which is taken for the convolution).

⟨*Decays: decay chain: TBP*⟩+≡

```
    procedure :: evaluate => decay_chain_evaluate
```

⟨*Decays: procedures*⟩+≡

```
    subroutine decay_chain_evaluate (chain)
      class(decay_chain_t), intent(inout) :: chain
      call evaluate (chain%last)
      call evaluator_receive_momenta (chain%correlated_trace)
      call chain%correlated_trace%evaluate ()
    contains
      recursive subroutine evaluate (entry)
        type(decay_chain_entry_t), intent(inout), pointer :: entry
        if (associated (entry)) then
           call evaluate (entry%previous)
           call entry%receive_kinematics ()
           call entry%evaluate_trace ()
           call entry%evaluate_event_data ()
        end if
      end subroutine evaluate
    end subroutine decay_chain_evaluate
```

Return the probability of a decay chain. This is given as the trace of the density matrix with intermediate helicity correlations, normalized by the product of the uncorrelated density matrix traces. This works only if an event has been

evaluated and the `correlated_trace` evaluator is filled. By definition, this evaluator has only one matrix element, and this must be real.

⟨*Decays: decay chain: TBP*⟩+≡
```
procedure :: get_probability => decay_chain_get_probability
```

⟨*Decays: procedures*⟩+≡
```
function decay_chain_get_probability (chain) result (x)
  class(decay_chain_t), intent(in) :: chain
  real(default) :: x
  x = evaluator_get_matrix_element (chain%correlated_trace, 1)
end function decay_chain_get_probability
```

17.2.12 Decay as Event Transform

The `evt_decay` object combines decay configuration, decay tree, and chain in a single object, as an implementation of the `evt` (event transform) abstract type.

⟨*Decays: public*⟩≡
```
public :: evt_decay_t
```

⟨*Decays: types*⟩+≡
```
type, extends (evt_t) :: evt_decay_t
  type(decay_root_config_t) :: decay_root_config
  type(decay_root_t) :: decay_root
  type(decay_chain_t) :: decay_chain
 contains
 ⟨Decays: evt decay: TBP⟩
end type evt_decay_t
```

Output. We display the currently selected decay tree, which includes configuration data, and the decay chain, i.e., the evaluators.

⟨*Decays: evt decay: TBP*⟩≡
```
procedure :: write => evt_decay_write
```

⟨*Decays: procedures*⟩+≡
```
subroutine evt_decay_write (object, unit, &
     show_decay_tree, &
     show_processes, &
     verbose)
  class(evt_decay_t), intent(in) :: object
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: show_decay_tree, show_processes, verbose
  logical :: dec, prc, verb
  integer :: u
  u = output_unit (unit)
  dec = .true.;  if (present (show_decay_tree))  dec = show_decay_tree
  prc = .false.;  if (present (show_processes))  prc = show_processes
  verb = .false.;  if (present (verbose))  verb = verbose
  call write_separator_double (u)
  write (u, "(1x,A)")  "Event transform: partonic decays"
  call write_separator_double (u)
  call object%base_write (u)
  if (dec) then
     call write_separator (u)
```

2359

```
          call object%decay_root%write (u)
          if (verb) then
             call object%decay_chain%write (u)
          end if
          if (prc) then
             call object%decay_root%write_process_instances (u, verb)
          end if
       else
          call write_separator_double (u)
       end if
    end subroutine evt_decay_write
```

Connect with a process instance and process. This initializes the decay config-
uration. The process stack is used to look for process objects that implement
daughter decays.

When all processes are assigned, configure the decay tree instance, using the
decay tree configuration. First obtain the branching ratios, then allocate the
decay tree. This is done once for all events.

⟨*Decays: evt decay: TBP*⟩+≡
```
    procedure :: connect => evt_decay_connect
```

⟨*Decays: procedures*⟩+≡
```
    subroutine evt_decay_connect (evt, process_instance, model, process_stack)
      class(evt_decay_t), intent(inout), target :: evt
      type(process_instance_t), intent(in), target :: process_instance
      type(model_t), intent(in), target :: model
      type(process_stack_t), intent(in), optional :: process_stack
      call evt%base_connect (process_instance, model)
      call evt%decay_root_config%connect (process_instance%process, &
           model, process_stack, process_instance)
      call evt%decay_root_config%compute ()
      call evt%decay_root%init (evt%decay_root_config, evt%process_instance)
    end subroutine evt_decay_connect
```

Prepare a new event: Select a decay chain and build the corresponding chain
object.

⟨*Decays: evt decay: TBP*⟩+≡
```
    procedure :: prepare_new_event => evt_decay_prepare_new_event
```

⟨*Decays: procedures*⟩+≡
```
    subroutine evt_decay_prepare_new_event (evt, i_mci, i_term)
      class(evt_decay_t), intent(inout) :: evt
      integer, intent(in) :: i_mci, i_term
      call evt%reset ()
      evt%decay_root%selected_mci = i_mci
      evt%decay_root%selected_term = i_term
      call evt%decay_root%select_chain ()
      call evt%decay_chain%build (evt%decay_root)
    end subroutine evt_decay_prepare_new_event
```

Generate a weighted event and assign the resulting weight (probability). We
use a chain initialized by the preceding subroutine, fill it with momenta and

evaluate.

⟨*Decays: evt decay: TBP*⟩+≡
```
    procedure :: generate_weighted => evt_decay_generate_weighted
```

⟨*Decays: procedures*⟩+≡
```
    subroutine evt_decay_generate_weighted (evt, probability)
      class(evt_decay_t), intent(inout) :: evt
      real(default), intent(out) :: probability
      call evt%decay_root%generate ()
      if (signal_is_pending ())  return
      call evt%decay_chain%evaluate ()
      probability = evt%decay_chain%get_probability ()
    end subroutine evt_decay_generate_weighted
```

To create a usable event, we have to transform the interaction into a particle
set; this requires factorization for the correlated density matrix, according to
the factorization mode.

⟨*Decays: evt decay: TBP*⟩+≡
```
    procedure :: make_particle_set => evt_decay_make_particle_set
```

⟨*Decays: procedures*⟩+≡
```

Testbed

As a variation of the `prepare_test_process` routine used elsewhere, we define
here a routine that creates two processes (scattering $ss \to ss$ and decay $s \to f\bar{f}$),
compiles and integrates them and prepares for event generation.

⟨*Decays: public*⟩+≡
```
    public :: prepare_testbed
```

⟨*Decays: tests*⟩+≡
```
    subroutine prepare_testbed &
         (lib, process_stack, model_list, model, prefix, os_data, &
          scattering, decay, decay_rest_frame)
      type(process_library_t), intent(out), target :: lib
      type(process_stack_t), intent(out) :: process_stack
      type(model_list_t), intent(out) :: model_list
      type(model_t), pointer, intent(out) :: model
      type(string_t), intent(in) :: prefix
```

```
type(os_data_t), intent(in) :: os_data

Read in the LHE file opened in unit `u` and add the final particles to the `particle_set`, the outgoing particles of the existing `particle_set` are set to be virtual before the outgoing particles from the LHEF are added to the `particle_set` as outgoing particles. At the same time, it is searched for pairs of existing and new particles with equal momenta and PDG code, these pairs are marked as connected. All remaining existing former outgoing particles are set to be the mothers of all remaining new outgoing particles.

  call evt%reset ()
end subroutine evt_shower_prepare_new_event
```

Here we take the particle set from the previous event transform (assuming that there is always one) and apply the shower algorithm. The result is stored in the event transform of the current object. We always return a probability of unity as we don't have the analytic weight of the combination of shower, MLM matching and hadronization. A subdivision into multiple event transformations might be useful. Invalid or vetoed events have to be discarded by the caller which is why we mark the particle set as invalid.

    end subroutine evt_shower_make_particle_set
```

Matching and hadronization functions

The HEPRUP (event) common block is needed for the interface to the shower. Filling of it is triggered by some output file formats. If these are not present, the common block is filled with some dummy information. Be generous with the number of processes in HEPRUP so that PYTHIA only rarely needs to be reinitialized in case events with higher process ids are generated.

17.4.1 Event configuration

The parameters govern the transformation of an event to a particle set.

The `safety_factor` reduces the acceptance probability for unweighting. If greater than one, excess events become less likely, but the reweighting efficiency also drops.

The `sigma` and `n` values, if nontrivial, allow for reweighting the events according to the requested `norm_mode`.

Various `parse_node_t` objects are taken from the SINDARIN input. They encode expressions that apply to the current event. The workspaces for evaluating those expressions are set up in the `event_expr_t` objects. Note that these are really pointers, so the actual nodes are not stored inside the event object.

⟨*Events: types*⟩≡
```
type :: event_config_t

```

17.4.2   Event normalization

The parameters for event normalization. For unweighted events, `NORM_UNIT` is intended as default, while for weighted events, it is `NORM_SIGMA`.

Note: the unit test for this is in `eio_data_2` below.

⟨*Events: parameters*⟩≡
```
    integer, parameter, public :: NORM_UNDEFINED = 0
    integer, parameter, public :: NORM_UNIT = 1
    integer, parameter, public :: NORM_N_EVT = 2
    integer, parameter, public :: NORM_SIGMA = 3
    integer, parameter, public :: NORM_S_N = 4
```

These functions translate between the user representation and the internal one.

⟨*Events: public*⟩≡
```
    public :: event_normalization_mode
    public :: event_normalization_string
```

⟨*Events: procedures*⟩+≡
```
    function event_normalization_mode (string, unweighted) result (mode)
      integer :: mode
      type(string_t), intent(in) :: string
      logical, intent(in) :: unweighted
      select case (lower_case (char (string)))
      case ("auto")
         if (unweighted) then
            mode = NORM_UNIT
         else
            mode = NORM_SIGMA
```

```
         end if
      case ("1")
         mode = NORM_UNIT
      case ("1/n")
         mode = NORM_N_EVT
      case ("sigma")
         mode = NORM_SIGMA
      case ("sigma/n")
         mode = NORM_S_N
      case default
         call msg_fatal ("Event normalization: unknown value '" &
              // char (string) // "'")
      end select
   end function event_normalization_mode

   function event_normalization_string (norm_mode) result (string)
     integer, intent(in) :: norm_mode
     type(string_t) :: string
     select case (norm_mode)
     case (NORM_UNDEFINED); string = "[undefined]"
     case (NORM_UNIT);      string = "'1'"
     case (NORM_N_EVT);     string = "'1/n'"
     case (NORM_SIGMA);     string = "'sigma'"
     case (NORM_S_N);       string = "'sigma/n'"
     case default;          string = "???"
     end select
   end function event_normalization_string
```

We place this here as a generic helper, so we can update event weights whenever we need, not just in connection with an event sample data object.

⟨*Events: public*⟩+≡
```
    public :: event_normalization_update
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_normalization_update (weight, sigma, n, mode_new, mode_old)
      real(default), intent(inout) :: weight
      real(default), intent(in) :: sigma
      integer, intent(in) :: n
      integer, intent(in) :: mode_new, mode_old
      if (mode_new /= mode_old) then
         if (sigma > 0 .and. n > 0) then
            weight = weight / factor (mode_old) * factor (mode_new)
         else
            call msg_fatal ("Event normalization update: null sample")
         end if
      end if
    contains
      function factor (mode)
        real(default) :: factor
        integer, intent(in) :: mode
        select case (mode)
        case (NORM_UNIT);  factor = 1._default
        case (NORM_N_EVT); factor = 1._default / n
        case (NORM_SIGMA); factor = sigma
```

```
      case (NORM_S_N);    factor = sigma / n
      case default
         call msg_fatal ("Event normalization update: undefined mode")
      end select
    end function factor
  end subroutine event_normalization_update
```

17.4.3 The event type

Each event has a single elementary process as its core. This process may be dressed by a shower, a decay chain etc. For this core we implement pointers to a process instance.

The actual (dressed) event record is implemented as a `particle_set` object.

A list of event transforms (class `evt_t`) transform the connected interactions of the process instance into the final particle set. In this list, the first transform is always the trivial one, which just factorizes the process instance. Subsequent transforms may apply decays, etc. The `particle_set` pointer identifies the particle set that we want to be analyzed and returned by the event, usually the last one.

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

The `sqme` and `weight` values mirror corresponding values in the `expr` subobject. The idea is that when generating or reading events, the event record is filled first, then the `expr` object acquires copies. These copies are used for writing events and as targets for pointer variables in the analysis expression.

All data that involve user-provided expressions (selection, reweighting, analysis) are handled by the `expr` subobject. In particular, evaluating the event-selection expression sets the `passed` flag. Furthermore, the `expr` subobject collects data that can be used in the analysis and should be written to file, including copies of `sqme` and `weight`.

⟨*Events: public*⟩+≡
```
    public :: event_t
```

⟨*Events: types*⟩+≡
```

```

17.4.4 Initialization

Initialize: set configuration parameters, using a variable list. We do not call this **init**, because this method name will be used by a type extension.

The default normalization is `NORM_SIGMA`, since the default generation mode is weighted.

For unweighted events, we may want to a apply a safety factor to event rejection. (By default, this factor is unity and can be ignored.)

We also allocate the trivial event transform, which is always the first one.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: basic_init => event_init
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_init (event, var_list, n_alt)
```

```
      class(event_t), intent(out) :: event
      type(var_list_t), intent(in), optional :: var_list
      integer, intent(in), optional :: n_alt
      type(string_t) :: norm_string
      logical :: polarized_events
      if (present (var_list)) then
         event%config%unweighted = var_list_get_lval (var_list, &
              var_str ("?unweighted"))
         norm_string = var_list_get_sval (var_list, &
              var_str ("$sample_normalization"))
         event%config%norm_mode = &
              event_normalization_mode (norm_string, event%config%unweighted)
         polarized_events = &
              var_list_get_lval (var_list, var_str ("?polarized_events"))
         if (polarized_events) then
            event%config%factorization_mode = FM_SELECT_HELICITY
         else
            event%config%factorization_mode = FM_IGNORE_HELICITY
         end if
         if (event%config%unweighted) then
            event%config%safety_factor = var_list_get_rval (var_list, &
                 var_str ("safety_factor"))
         end if
      else
         event%config%norm_mode = NORM_SIGMA
      end if
      if (present (n_alt)) then
         event%n_alt = n_alt
         allocate (event%sqme_alt (n_alt))
         allocate (event%weight_alt (n_alt))
         call event%expr%init (n_alt)
      end if
      allocate (evt_trivial_t :: event%transform_first)
      event%transform_last => event%transform_first
    end subroutine event_init
```

Set the `sigma` and `n` values in the configuration record that determine non-standard event normalizations. If these numbers are not set explicitly, the default value for both is unity, and event renormalization has no effect.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: set_sigma => event_set_sigma
    procedure :: set_n => event_set_n
```

⟨*Events: procedures*⟩+≡
```
    elemental subroutine event_set_sigma (event, sigma)
      class(event_t), intent(inout) :: event
      real(default), intent(in) :: sigma
      event%config%sigma = sigma
    end subroutine event_set_sigma

    elemental subroutine event_set_n (event, n)
      class(event_t), intent(inout) :: event
      integer, intent(in) :: n
      event%config%n = n
```

```
      end subroutine event_set_n
```

Append an event transform (decays, etc.). The transform is not yet connected to a process. The transform is then considered to belong to the event object, and will be finalized together with it. The original pointer is removed.

We can assume that the trivial transform is already present in the event object, at least.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: import_transform => event_import_transform
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_import_transform (event, evt)
      class(event_t), intent(inout) :: event
      class(evt_t), intent(inout), pointer :: evt
      event%transform_last%next => evt
      evt%previous => event%transform_last
      event%transform_last => evt
      evt => null ()
    end subroutine event_import_transform
```

We link the event to an existing process instance. This includes the variable list, which is linked to the process variable list. Note that this is not necessarily identical to the variable list used for event initialization.

The variable list will contain pointers to **event** subobjects, therefore the **target** attribute.

Once we have a process connected, we can use it to obtain an event generator instance.

The model and process stack may be needed by event transforms. The current model setting may be different from the model in the process (regarding unstable particles, etc.). The process stack can be used for assigning extra processes that we need for the event transforms.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: connect => event_connect
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_connect (event, process_instance, model, process_stack)
      class(event_t), intent(inout), target :: event
      type(process_instance_t), intent(in), target :: process_instance
      type(model_t), intent(in), target :: model
      type(process_stack_t), intent(in), optional :: process_stack
      type(string_t) :: id
      integer :: num_id
      class(evt_t), pointer :: evt
      event%process => process_instance%process
      event%instance => process_instance
      id = event%process%get_id ()
      if (id /= "")  call event%expr%set_process_id (id)
      num_id = event%process%get_num_id ()
      if (num_id /= 0)  call event%expr%set_process_num_id (num_id)
      call event%expr%setup_vars (event%process%get_sqrts ())
      call event%expr%link_var_list (event%process%get_var_list_ptr ())
      call event%process%make_rng (event%rng)
```

```
      evt => event%transform_first
      do while (associated (evt))
          call evt%connect (process_instance, model, process_stack)
          evt => evt%next
      end do
   end subroutine event_connect
```

Set the parse nodes for the associated expressions, individually. The parse-node
pointers may be null.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: set_selection => event_set_selection
    procedure :: set_reweight => event_set_reweight
    procedure :: set_analysis => event_set_analysis
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_set_selection (event, pn_selection)
      class(event_t), intent(inout) :: event
      type(parse_node_t), intent(in), pointer :: pn_selection
      event%config%pn_selection => pn_selection
    end subroutine event_set_selection

    subroutine event_set_reweight (event, pn_reweight)
      class(event_t), intent(inout) :: event
      type(parse_node_t), intent(in), pointer :: pn_reweight
      event%config%pn_reweight => pn_reweight
    end subroutine event_set_reweight

    subroutine event_set_analysis (event, pn_analysis)
      class(event_t), intent(inout) :: event
      type(parse_node_t), intent(in), pointer :: pn_analysis
      event%config%pn_analysis => pn_analysis
    end subroutine event_set_analysis
```

Create evaluation trees from the parse trees. The `target` attribute is required
because the expressions contain pointers to event subobjects.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: setup_expressions => event_setup_expressions
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_setup_expressions (event)
      class(event_t), intent(inout), target :: event
      call event%expr%setup_selection (event%config%pn_selection)
      call event%expr%setup_analysis (event%config%pn_analysis)
      call event%expr%setup_reweight (event%config%pn_reweight)
    end subroutine event_setup_expressions
```

17.4.5 Evaluation

To fill the `particle_set`, i.e., the event record proper, we have to apply all
event transforms in order. The last transform should fill its associated particle
set, factorizing the state matrix according to the current settings. There are
several parameters in the event configuration that control this.

We always fill the particle set for the first transform (the hard process) and the last transform, if different from the first (the fully dressed process).

Each event transform is an event generator of its own. We choose to generate an *unweighted* event for each of them, even if the master event is assumed to be weighted. Thus, the overall event weight is the one of the hard process only. (There may be more options in future extensions.)

We can generate the two random numbers that the factorization needs. For testing purpose, we allow for providing them explicitly, as an option.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: evaluate_transforms => event_evaluate_transforms
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_evaluate_transforms (event, r)
      class(event_t), intent(inout) :: event
      real(default), dimension(:), intent(in), optional :: r
      class(evt_t), pointer :: evt
      integer :: i_term
      event%particle_set_exists = .false.
      call event%check ()
      if (event%instance%is_complete_event ()) then
         call event%instance%select_i_term (i_term)
         event%selected_i_term = i_term
         evt => event%transform_first
         do while (associated (evt))
            call evt%prepare_new_event &
                 (event%selected_i_mci, event%selected_i_term)
            evt => evt%next
         end do
         evt => event%transform_first
         do while (associated (evt))
            call evt%generate_unweighted ()
            if (signal_is_pending ())  return
            call evt%make_particle_set (event%config%factorization_mode, &
                 event%config%keep_correlations)
            if (signal_is_pending ())  return
            if (.not. evt%particle_set_exists)  exit
            evt => evt%next
         end do
         evt => event%transform_last
         if (associated (evt) .and. evt%particle_set_exists) then
            event%particle_set => evt%particle_set
            call event%accept_particle_set ()
         end if
      end if
    end subroutine event_evaluate_transforms
```

Evaluate the event-related expressions, given a valid `particle_set`. If `update_sqme` is set, we use the process instance for the `sqme_prc` value. The `sqme_ref` value is always taken from the event record.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: evaluate_expressions => event_evaluate_expressions
```

⟨*Events: procedures*⟩+≡

```
subroutine event_evaluate_expressions (event)
  class(event_t), intent(inout) :: event
  if (event%particle_set_exists) then
     call event%expr%fill_subevt (event%particle_set)
  end if
  if (event%weight_ref_is_known) then
     call event%expr%set (weight_ref = event%weight_ref)
  end if
  if (event%weight_prc_is_known) then
     call event%expr%set (weight_prc = event%weight_prc)
  end if
  if (event%excess_prc_is_known) then
     call event%expr%set (excess_prc = event%excess_prc)
  end if
  if (event%sqme_ref_is_known) then
     call event%expr%set (sqme_ref = event%sqme_ref)
  end if
  if (event%sqme_prc_is_known) then
     call event%expr%set (sqme_prc = event%sqme_prc)
  end if
  if (event%particle_set_exists) then
     call event%expr%evaluate &
          (event%passed, event%reweight, event%analysis_flag)
     event%selection_evaluated = .true.
  end if
end subroutine event_evaluate_expressions
```

Set alternate sqme and weight arrays. This should be merged with the previous routine, if the expressions are allowed to refer to these values.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: store_alt_values => event_store_alt_values
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_store_alt_values (event)
      class(event_t), intent(inout) :: event
      if (event%weight_alt_is_known) then
         call event%expr%set (weight_alt = event%weight_alt)
      end if
      if (event%sqme_alt_is_known) then
         call event%expr%set (sqme_alt = event%sqme_alt)
      end if
    end subroutine event_store_alt_values
```

17.4.6 Reset to empty state

Applying this, current event contents are marked as incomplete but are not deleted. In particular, the initialization is kept.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: reset => event_reset
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_reset (event)
```

```
     class(event_t), intent(inout) :: event
     class(evt_t), pointer :: evt
     event%selected_i_mci = 0
     event%selected_i_term = 0
     event%selected_channel = 0
     event%is_complete = .false.
     event%particle_set_exists = .false.
     event%sqme_ref_is_known = .false.
     event%sqme_prc_is_known = .false.

                   excess_prc = event%instance%get_excess () &
                   )
           end if
        end if
      end subroutine event_import_instance_results
```

Duplicate the instance result / the reference result in the event record.

⟨*Events: event: TBP*⟩+≡
```
      procedure :: accept_sqme_ref => event_accept_sqme_ref
      procedure :: accept_sqme_prc => event_accept_sqme_prc
      procedure :: accept_weight_ref => event_accept_weight_ref
      procedure :: accept_weight_prc => event_accept_weight_prc
```

⟨*Events: procedures*⟩+≡
```
      subroutine event_accept_sqme_ref (event)
        class(event_t), intent(inout) :: event
        if (event%sqme_ref_is_known) then
           call event%set (sqme_prc = event%sqme_ref)
        end if
      end subroutine event_accept_sqme_ref
```

```
      subroutine event_accept_sqme_prc (event)
        class(event_t), intent(inout) :: event
        if (event%sqme_prc_is_known) then
           call event%set (sqme_ref = event%sqme_prc)
        end if
      end subroutine event_accept_sqme_prc

      subroutine event_accept_weight_ref (event)
        class(event_t), intent(inout) :: event
        if (event%weight_ref_is_known) then
           call event%set (weight_prc = event%weight_ref)
        end if
      end subroutine event_accept_weight_ref

      subroutine event_accept_weight_prc (event)
        class(event_t), intent(inout) :: event
        if (event%weight_prc_is_known) then
           call event%set (weight_ref = event%weight_prc)
        end if
      end subroutine event_accept_weight_prc
```

Update the weight normalization, just after generation. Unweighted and weighted
events are generated with a different default normalization. The intended nor-
malization is stored in the configuration record.

⟨*Events: event: TBP*⟩+≡
```
      procedure :: update_normalization => event_update_normalization
```

⟨*Events: procedures*⟩+≡
```
      subroutine event_update_normalization (event, mode_ref)
        class(event_t), intent(inout) :: event
        integer, intent(in), optional :: mode_ref
        integer :: mode_old
        if (present (mode_ref)) then
           mode_old = mode_ref
        else if (event%config%unweighted) then
           mode_old = NORM_UNIT
        else
           mode_old = NORM_SIGMA
        end if
        call event_normalization_update (event%weight_prc, &
             event%config%sigma, event%config%n, &
             mode_new = event%config%norm_mode, &
             mode_old = mode_old)
        call event_normalization_update (event%excess_prc, &
             event%config%sigma, event%config%n, &
             mode_new = event%config%norm_mode, &
             mode_old = mode_old)
      end subroutine event_update_normalization
```

The event is complete if it has a particle set plus valid entries for the sqme and
weight values.

⟨*Events: event: TBP*⟩+≡
```
      procedure :: check => event_check
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_check (event)
      class(event_t), intent(inout) :: event
      event%is_complete = event%particle_set_exists &
           .and. event%sqme_ref_is_known &
           .and. event%sqme_prc_is_known &
           .and. event%weight_ref_is_known &
           .and. event%weight_prc_is_known
      if (event%n_alt /= 0) then
         event%is_complete = event%is_complete &
              .and. event%sqme_alt_is_known &
              .and. event%weight_alt_is_known
      end if
    end subroutine event_check
```

17.4.8   Generation

Assuming that we have a valid process associated to the event, we generate an event. We complete the event data, then factorize the spin density matrix and transfer it to the particle set.

When done, we retrieve squared matrix element and weight. In case of explicit generation, the reference values coincide with the process values, so we `accept` the latter.

The explicit random number argument `r` should be generated by a random-number generator. It is taken for the factorization algorithm, bypassing the event-specific random-number generator. This is useful for deterministic testing.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: generate => event_generate
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_generate (event, i_mci, r)
      class(event_t), intent(inout) :: event
      integer, intent(in) :: i_mci
      real(default), dimension(:), intent(in), optional :: r
      call event%reset ()
      event%selected_i_mci = i_mci
      if (event%config%unweighted) then
         call event%process%generate_unweighted_event (event%instance, i_mci)
         if (signal_is_pending ()) return
         call event%instance%evaluate_event_data ()
         call event%instance%normalize_weight ()
      else
         call event%process%generate_weighted_event (event%instance, i_mci)
         if (signal_is_pending ()) return
         call event%instance%evaluate_event_data ()
      end if
      event%selected_channel = event%instance%get_channel ()
      call event%import_instance_results ()
      call event%accept_sqme_prc ()
      call event%update_normalization ()
      call event%accept_weight_prc ()
      call event%evaluate_transforms (r)
```

2433

```
      if (signal_is_pending ())  return
      call event%check ()
   end subroutine event_generate
```

Get a copy of the particle set belonging to the hard process.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: get_particle_set_hard_proc => event_get_particle_set_hard_proc
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_get_particle_set_hard_proc (event, pset)
      class(event_t), intent(in) :: event
      type(particle_set_t), intent(out) :: pset
      class(evt_t), pointer :: evt
      evt => event%transform_first
      pset = evt%particle_set
    end subroutine event_get_particle_set_hard_proc
```

17.4.9   Recovering an event

Select MC group, term, and integration channel.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: select => event_select
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_select (event, i_mci, i_term, channel)
      class(event_t), intent(inout) :: event
      integer, intent(in) :: i_mci, i_term, channel
      if (associated (event%instance)) then
         event%selected_i_mci = i_mci
         event%selected_i_term = i_term
         event%selected_channel = channel
      else
         call msg_bug ("Event: select term: process instance undefined")
      end if
    end subroutine event_select
```

Copy a particle set into the event record.

We deliberately use the first (the trivial) transform for this, i.e., the hard process. Thus, with the current implementation, event readers can only be used for reading hard events. However, once we have reconstructed the master process, we may apply all event transforms to generate a fully dressed event.

Since this makes all subsequent event transforms invalid, we call `reset` on them.

⟨*Events: event: TBP*⟩+≡
```
    procedure :: set_particle_set_hard_proc => event_set_particle_set_hard_proc
```

⟨*Events: procedures*⟩+≡
```
    subroutine event_set_particle_set_hard_proc (event, particle_set)
      class(event_t), intent(inout) :: event
      type(particle_set_t), intent(in) :: particle_set
      class(evt_t), pointer :: evt
      evt => event%transform_first
```

```
         call evt%set_particle_set (particle_set, &
              event%selected_i_mci, event%selected_i_term)
         event%particle_set => evt%particle_set
         call event%accept_particle_set ()
         evt => evt%next
         do while (associated (evt))
            call evt%reset ()
            evt => evt%next
         end do
      end subroutine event_set_particle_set_hard_proc
```

Mark the particle set as existing, assuming that it has just been filled somehow.

⟨*Events: event: TBP*⟩+≡
```
      procedure :: accept_particle_set => event_accept_particle_set
```

⟨*Events: procedures*⟩+≡
```
      subroutine event_accept_particle_set (event)
        class(event_t), intent(inout) :: event
        event%particle_set_exists = .true.
      end subroutine event_accept_particle_set
```

Here we try to recover an event from the `particle_set` subobject and recalculate the structure functions and matrix elements. We have the appropriate `process` object and an initialized `process_instance` at hand, so beam and configuration data are known. From the `particle_set`, we get the momenta.

The quantum-number information may be incomplete, e.g., helicity information may be partial or absent. We recover the event just from the momentum configuration.

We do not transfer the matrix element from the process instance to the event record, as we do when generating an event. The event record may contain the matrix element as read from file, and the current calculation may use different parameters. We thus can compare old and new values.

The event `weight` may also be known already. If yes, we pass it to the `evaluate_event_data` procedure. It should already be normalized. If we have an `weight_factor` value, we obtain the event weight by multiplying the computed `sqme` by this factor. Otherwise, we make use of the MCI setup (which should be valid then) to compute the event weight, and we should normalize the result just as when generating events.

Evaluating event expressions must also be done separately.

⟨*Events: event: TBP*⟩+≡
```
      procedure :: recalculate => event_recalculate
```

⟨*Events: procedures*⟩+≡
```
      subroutine event_recalculate &
           (event, update_sqme, weight_factor, recover_beams)
        class(event_t), intent(inout) :: event
        logical, intent(in) :: update_sqme
        real(default), intent(in), optional :: weight_factor
        logical, intent(in), optional :: recover_beams
        integer :: i_mci, i_term, channel
        if (event%particle_set_exists) then
           i_mci = event%selected_i_mci
```

```
            i_term = event%selected_i_term
            channel = event%selected_channel
            if (i_mci == 0 .or. i_term == 0 .or. channel == 0) then
                call msg_bug ("Event: recalculate: undefined selection parameters")
            end if
            call event%instance%choose_mci (i_mci)
            call event%instance%set_trace (event%particle_set, i_term, recover_beams)
            call event%instance%recover (channel, i_term, update_sqme)
            if (signal_is_pending ())  return
            if (update_sqme .and. present (weight_factor)) then
                call event%instance%evaluate_event_data &
                     (weight = event%instance%get_sqme () * weight_factor)
            else if (event%weight_ref_is_known) then
                call event%instance%evaluate_event_data &
                     (weight = event%weight_ref)
            else
                call event%process%recover_event (event%instance, i_term)
                if (signal_is_pending ())  return
                call event%instance%evaluate_event_data ()
                if (event%config%unweighted) then
                    call event%instance%normalize_weight ()
                end if
            end if
            if (signal_is_pending ())  return
            if (update_sqme) then
                call event%import_instance_results ()
            else

      class(event_t), intent(in) :: event
      type(process_t), pointer :: ptr
      ptr => event%process
    end function event_get_process_ptr
```

Tell whether the particle set is defined:

⟨*Events: event: TBP*⟩+≡
```
    procedure :: has_particle_set => event_has_particle_set
```

⟨Events: procedures⟩+≡
```
    function event_has_particle_set (event) result (flag)
      class(event_t), intent(in) :: event
      logical :: flag
      flag = event%particle_set_exists
    end function event_has_particle_set
```

Pointer to the particle set.

⟨Events: event: TBP⟩+≡
```
    procedure :: get_particle_set_ptr => event_get_particle_set_ptr
```

⟨Events: procedures⟩+≡
```
    function event_get_particle_set_ptr (event) result (ptr)
      class(event_t), intent(in), target :: event
      type(particle_set_t), pointer :: ptr
      ptr => event%particle_set
    end function event_get_particle_set_ptr
```

Return the current values of indices: the MCI group of components, the term index (different terms corresponding, potentially, to different effective kinematics), and the MC integration channel. The `i_mci` call is delegated to the current process instance.

⟨Events: event: TBP⟩+≡
```
    procedure :: get_i_mci => event_get_i_mci
    procedure :: get_i_term => event_get_i_term
    procedure :: get_channel => event_get_channel
```

⟨Events: procedures⟩+≡
```
    function event_get_i_mci (event) result (i_mci)
      class(event_t), intent(in) :: event
      integer :: i_mci
      i_mci = event%selected_i_mci
    end function event_get_i_mci

    function event_get_i_term (event) result (i_term)
      class(event_t), intent(in) :: event
      integer :: i_term
      i_term = event%selected_i_term
    end function event_get_i_term

    function event_get_channel (event) result (channel)
      class(event_t), intent(in) :: event
      integer :: channel
      channel = event%selected_channel
    end function event_get_channel
```

Return the currently selected normalization mode, or alternate normalization mode.

⟨Events: event: TBP⟩+≡
```
    procedure :: get_norm_mode => event_get_norm_mode
```

⟨*Events: procedures*⟩+≡
```
elemental function event_get_norm_mode (event) result (norm_mode)
  class(event_t), intent(in) :: event
  integer :: norm_mode
  norm_mode = event%config%norm_mode
end function event_get_norm_mode
```

Return the kinematical weight, defined as the ratio of event weight and squared matrix element.

⟨*Events: event: TBP*⟩+≡
```
procedure :: get_kinematical_weight => event_get_kinematical_weight
```

⟨*Events: procedures*⟩+≡
```
function event_get_kinematical_weight (event) result (f)
  class(event_t), intent(in) :: event
  real(default) :: f
  if (event%sqme_ref_is_known .and. event%weight_ref_is_known &
       .and. event%sqme_ref /= 0) then
     f = event%weight_ref / event%sqme_ref
  else
     f = 0
  end if
end function event_get_kinematical_weight
```

Return data used by external event formats.

⟨*Events: event: TBP*⟩+≡
```
procedure :: get_fac_scale => event_get_fac_scale
procedure :: get_alpha_s => event_get_alpha_s
```

⟨*Events: procedures*⟩+≡
```
function event_get_fac_scale (event) result (fac_scale)
  class(event_t), intent(in) :: event
  real(default) :: fac_scale
  fac_scale = event%instance%get_fac_scale (event%selected_i_term)
end function event_get_fac_scale

function event_get_alpha_s (event) result (alpha_s)
  class(event_t), intent(in) :: event
  real(default) :: alpha_s
  alpha_s = event%instance%get_alpha_s (event%selected_i_term)
end function event_get_alpha_s
```

Eliminate numerical noise in the `subevt` expression and in the event transforms (which includes associated process instances).

⟨*Events: public*⟩+≡
```
public :: pacify
```

⟨*Events: interfaces*⟩≡
```
interface pacify

Chapter 18

Matrix Element Implementations

In this chapter, we define concrete implementations for the workflow, from matrix-element code generation via matrix-element access to integration and event generation.

18.1 Template matrix elements

Here, we provide template matrix elements that are in structure very similar to O'MEGA matrix elements, but do not need its infrastructure. Per default, the matrix elements are flat, i.e. the have the constant value one. Analogous to the O'MEGA implementation, this section implements the interface to the templates (via the makefile) and the driver.

⟨prc_template_me.f90⟩≡
  ⟨*File header*⟩

  module prc_template_me

    use iso_c_binding !NODEP!
    use kinds !NODEP!
  ⟨*Use file utils*⟩
  ⟨*Use strings*⟩
    use limits, only: TAB !NODEP!
    use diagnostics !NODEP!
    use unit_tests
    use os_interface
    use lorentz !NODEP!
    use flavors
    use sm_qcd
    use interactions
    use variables
    use models

    use process_constants
    use prclib_interfaces

```
    use prc_core_def
    use particle_specifiers
    use process_libraries
    use prc_core
```

⟨*Standard module head*⟩

⟨*Template matrix elements: public*⟩

⟨*Template matrix elements: types*⟩

⟨*Template matrix elements: interfaces*⟩

```
contains
```

⟨*Template matrix elements: procedures*⟩

⟨*Template matrix elements: tests*⟩

```
end module prc_template_me
```

18.1.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

⟨*Template matrix elements: public*⟩≡
```
    public :: template_me_def_t
```

⟨*Template matrix elements: types*⟩≡
```
    type, extends (prc_core_def_t) :: template_me_def_t
      contains
      ⟨Template matrix elements: template ME def: TBP⟩
    end type template_me_def_t
```

⟨*Template matrix elements: template ME def: TBP*⟩≡
```
    procedure, nopass :: type_string => template_me_def_type_string
```

⟨*Template matrix elements: procedures*⟩≡
```
    function template_me_def_type_string () result (string)
      type(string_t) :: string
      string = "template"
    end function template_me_def_type_string
```

Initialization: allocate the writer for the template matrix element. Also set any data for this process that the writer needs.

⟨*Template matrix elements: template ME def: TBP*⟩+≡
```
    procedure :: init => template_me_def_init
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine template_me_def_init &
        (object, model, prt_in, prt_out, unity)
      class(template_me_def_t), intent(out) :: object
      type(model_t), intent(in), target :: model
      type(string_t), dimension(:), intent(in) :: prt_in
```

```
      type(string_t), dimension(:), intent(in) :: prt_out
      logical, intent(in) :: unity
      allocate (template_me_writer_t :: object%writer)
      select type (writer => object%writer)
      type is (template_me_writer_t)
         call writer%init (model, prt_in, prt_out, unity)
      end select
    end subroutine template_me_def_init
```

Write/read process- and method-specific data.

⟨*Template matrix elements: template ME def: TBP*⟩+≡
```
    procedure :: write => template_me_def_write
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine template_me_def_write (object, unit)
      class(template_me_def_t), intent(in) :: object
      integer, intent(in) :: unit
      select type (writer => object%writer)
      type is (template_me_writer_t)
         call writer%write (unit)
      end select
    end subroutine template_me_def_write
```

⟨*Template matrix elements: template ME def: TBP*⟩+≡
```
    procedure :: read => template_me_def_read
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine template_me_def_read (object, unit)
      class(template_me_def_t), intent(out) :: object
      integer, intent(in) :: unit
      call msg_bug &
           ("WHIZARD template process definition: input not supported (yet)")
    end subroutine template_me_def_read
```

Allocate the driver for template matrix elements.

⟨*Template matrix elements: template ME def: TBP*⟩+≡
```
    procedure :: allocate_driver => template_me_def_allocate_driver
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine template_me_def_allocate_driver (object, driver, basename)
      class(template_me_def_t), intent(in) :: object
      class(prc_core_driver_t), intent(out), allocatable :: driver
      type(string_t), intent(in) :: basename
      allocate (template_me_driver_t :: driver)
    end subroutine template_me_def_allocate_driver
```

We need code:

⟨*Template matrix elements: template ME def: TBP*⟩+≡
```
    procedure, nopass :: needs_code => template_me_def_needs_code
```

⟨*Template matrix elements: procedures*⟩+≡
```
    function template_me_def_needs_code () result (flag)
      logical :: flag
      flag = .true.
    end function template_me_def_needs_code
```

These are the features that a template matrix element provides.
⟨*Template matrix elements: template ME def: TBP*⟩+≡
```
    procedure, nopass :: get_features => template_me_def_get_features
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine template_me_def_get_features (features)
      type(string_t), dimension(:), allocatable, intent(out) :: features
      allocate (features (6))
      features = [ &
           var_str ("init"), &
           var_str ("update_alpha_s"), &
           var_str ("is_allowed"), &
           var_str ("new_event"), &
           var_str ("get_amplitude")]
    end subroutine template_me_def_get_features
```

The interface of the specific features.
⟨*Template matrix elements: interfaces*⟩≡
```
    abstract interface
       subroutine init_t (par) bind(C)
         import
         real(c_default_float), dimension(*), intent(in) :: par
       end subroutine init_t
    end interface

    abstract interface
       subroutine update_alpha_s_t (alpha_s) bind(C)
         import
         real(c_default_float), intent(in) :: alpha_s
       end subroutine update_alpha_s_t
    end interface

    abstract interface
       subroutine is_allowed_t (flv, hel, col, flag) bind(C)
         import
         integer(c_int), intent(in) :: flv, hel, col
         logical(c_bool), intent(out) :: flag
       end subroutine is_allowed_t
    end interface

    abstract interface
       subroutine new_event_t (p) bind(C)
         import
         real(c_default_float), dimension(0:3,*), intent(in) :: p
       end subroutine new_event_t
    end interface
```

```
      abstract interface
         subroutine get_amplitude_t (flv, hel, col, amp) bind(C)
            import
            integer(c_int), intent(in) :: flv, hel, col
            complex(c_default_complex), intent(out):: amp
         end subroutine get_amplitude_t
      end interface
```

Connect the template matrix element features with the process driver.

⟨*Template matrix elements: template ME def: TBP*⟩+≡
```
      procedure :: connect => template_me_def_connect
```

⟨*Template matrix elements: procedures*⟩+≡
```
      subroutine template_me_def_connect (def, lib_driver, i, proc_driver)
        class(template_me_def_t), intent(in) :: def
        class(prclib_driver_t), intent(in) :: lib_driver
        integer, intent(in) :: i
        class(prc_core_driver_t), intent(inout) :: proc_driver
        integer(c_int) :: pid, fid
        type(c_funptr) :: fptr
        select type (proc_driver)
        type is  (template_me_driver_t)
           pid = i
           fid = 1
           call lib_driver%get_fptr (pid, fid, fptr)
           call c_f_procpointer (fptr, proc_driver%init)
           fid = 2
           call lib_driver%get_fptr (pid, fid, fptr)
           call c_f_procpointer (fptr, proc_driver%update_alpha_s)
           fid = 3
           call lib_driver%get_fptr (pid, fid, fptr)
           call c_f_procpointer (fptr, proc_driver%is_allowed)
           fid = 4
           call lib_driver%get_fptr (pid, fid, fptr)
           call c_f_procpointer (fptr, proc_driver%new_event)
           fid = 5
           call lib_driver%get_fptr (pid, fid, fptr)
           call c_f_procpointer (fptr, proc_driver%get_amplitude)
        end select
      end subroutine template_me_def_connect
```

18.1.2 The Template Matrix element writer

Unlike O'MEGA, the template matrix element is directly written by the main
WHIZARD program, so there will be no entry in the makefile for calling an ex-
ternal program. The template matrix element writer is responsible for writing
interfaces and wrappers.

⟨*Template matrix elements: types*⟩+≡
```
      type, extends (prc_writer_f_module_t) :: template_me_writer_t
         type(model_t), pointer :: model => null ()
         type(string_t) :: model_name
         logical :: unity
```

2455

```
       type(string_t), dimension(:), allocatable :: prt_in
       type(string_t), dimension(:), allocatable :: prt_out
       integer :: n_in
       integer :: n_out
       integer :: n_tot
      contains
     ⟨Template matrix elements: template ME writer: TBP⟩
     end type template_me_writer_t
```

The reported type is the same as for the `template_me_def_t` type.

⟨*Template matrix elements: template ME writer: TBP*⟩≡
```
     procedure, nopass :: type_name => template_me_writer_type_name
```

⟨*Template matrix elements: procedures*⟩+≡
```
     function template_me_writer_type_name () result (string)
       type(string_t) :: string
       string = "template"
     end function template_me_writer_type_name
```

Taking into account the prefix for template ME module names.

⟨*Template matrix elements: template ME writer: TBP*⟩+≡
```
     procedure, nopass :: get_module_name => template_me_writer_get_module_name
```

⟨*Template matrix elements: procedures*⟩+≡
```
     function template_me_writer_get_module_name (id) result (name)
       type(string_t) :: name
       type(string_t), intent(in) :: id
       name = "tpr_" // id
     end function template_me_writer_get_module_name
```

Output. This is called by `template_me_def_write`.

⟨*Template matrix elements: template ME writer: TBP*⟩+≡
```
     procedure :: write => template_me_writer_write
```

⟨*Template matrix elements: procedures*⟩+≡
```
     subroutine template_me_writer_write (object, unit)
       class(template_me_writer_t), intent(in) :: object
       integer, intent(in) :: unit
       integer :: i, j
       write (unit, "(5x,A,I0)") "# incoming part. = ", object%n_in
       write (unit, "(7x,A)", advance="no") &
                             "     Initial state: "
       do i = 1, object%n_in - 1
          write (unit, "(1x,A)", advance="no") char (object%prt_in(i))
       end do
       write (unit, "(1x,A)") char (object%prt_in(object%n_in))
       write (unit, "(5x,A,I0)") "# outgoing part. = ", object%n_out
       write (unit, "(7x,A)", advance="no") &
                             "     Final state:   "
       do j = 1, object%n_out - 1
          write (unit, "(1x,A)", advance="no") char (object%prt_out(i))
       end do
       write (unit, "(1x,A)") char (object%prt_out(object%n_out))
       write (unit, "(5x,A,I0)") "# part. (total) = ", object%n_tot
```

```
    end subroutine template_me_writer_write
```

Initialize with process data.

⟨Template matrix elements: template ME writer: TBP⟩+≡
```
    procedure :: init => template_me_writer_init
```

⟨Template matrix elements: procedures⟩+≡
```
    subroutine template_me_writer_init (writer, model, &
         prt_in, prt_out, unity)
      class(template_me_writer_t), intent(out) :: writer
      type(model_t), intent(in), target :: model
      type(string_t), dimension(:), intent(in) :: prt_in
      type(string_t), dimension(:), intent(in) :: prt_out
      logical, intent(in) :: unity
      writer%model => model
      writer%model_name = model%get_name ()
      writer%n_in = size (prt_in)
      writer%n_out = size (prt_out)
      writer%n_tot = size (prt_in) + size (prt_out)
      allocate (writer%prt_in (size (prt_in)), source = prt_in)
      allocate (writer%prt_out (size (prt_out)), source = prt_out)
      writer%unity = unity
    end subroutine template_me_writer_init
```

The makefile is the driver file for the test matrix elements.

⟨Template matrix elements: template ME writer: TBP⟩+≡
```
    procedure :: write_makefile_code => template_me_write_makefile_code
```

⟨Template matrix elements: procedures⟩+≡
```
    subroutine template_me_write_makefile_code (writer, unit, id, os_data, testflag)
      class(template_me_writer_t), intent(in) :: writer
      integer, intent(in) :: unit
      type(string_t), intent(in) :: id
      type(os_data_t), intent(in) :: os_data
      logical, intent(in), optional :: testflag
      write (unit, "(5A)")  "SOURCES += ", char (id), ".f90"
      write (unit, "(5A)")  "OBJECTS += ", char (id), ".lo"
      write (unit, "(5A)")  "clean-", char (id), ":"
      write (unit, "(5A)")  TAB, "rm -f tpr_", char (id), ".mod"
      write (unit, "(5A)")  TAB, "rm -f ", char (id), ".lo"

```

18.1.3 Driver

⟨*Template matrix elements: types*⟩+≡

```
   type, extends (prc_core_driver_t) :: template_me_driver_t
     procedure(init_t), nopass, pointer :: &
          init => null ()
     procedure(update_alpha_s_t), nopass, pointer :: &
          update_alpha_s => null ()
     procedure(is_allowed_t), nopass, pointer :: &
          is_allowed => null ()
     procedure(new_event_t), nopass, pointer :: &
          new_event => null ()
     procedure(get_amplitude_t), nopass, pointer :: &
          get_amplitude => null ()
    contains
    ⟨Template matrix elements: template ME driver: TBP⟩
   end type template_me_driver_t
```

The reported type is the same as for the `template_me_def_t` type.

⟨*Template matrix elements: template ME driver: TBP*⟩≡
```
procedure, nopass :: type_name => template_me_driver_type_name
```

⟨*Template matrix elements: procedures*⟩+≡
```
function template_me_driver_type_name () result (string)
  type(string_t) :: string
  string = "template"
end function template_me_driver_type_name
```

18.1.4 High-level process definition

This procedure wraps the details filling a process-component definition entry as appropriate for an template matrix element.

  NOTE: For calling the `import_component` method, we must explicitly address the `process_def_t` parent object. The natural way to call the method of the extended type triggers a bug in gfortran 4.6. The string array arguments `prt_in` and `prt_out` become corrupted and cause a segfault.

⟨*Template matrix elements: public*⟩+≡
```
public :: template_me_make_process_component
```

⟨*Template matrix elements: procedures*⟩+≡
```
subroutine template_me_make_process_component (entry, component_index, &
      model, model_name, prt_in, prt_out, unity)
  class(process_def_entry_t), intent(inout) :: entry
  integer, intent(in) :: component_index
  type(string_t), intent(in) :: model_name
  type(model_t), intent(in), target :: model
  type(string_t), dimension(:), intent(in) :: prt_in
  type(string_t), dimension(:), intent(in) :: prt_out
  logical, intent(in) :: unity
  class(prc_core_def_t), allocatable :: def
  allocate (template_me_def_t :: def)
  select type (def)
  type is (template_me_def_t)
     call def%init (model, prt_in, prt_out, unity)
  end select
  call entry%process_def_t%import_component (component_index, &
      n_out = size (prt_out), &
      prt_in  = new_prt_spec (prt_in), &
      prt_out = new_prt_spec (prt_out), &
      method = var_str ("template"), &
      variant = def)
end subroutine template_me_make_process_component
```

18.1.5 The `prc_template_me_t` wrapper

This is an instance of the generic `prc_core_t` object. It contains a pointer to the process definition (`template_me_def_t`), a data component (`process_constants_t`), and the matrix-element driver (`template_me_driver_t`).

⟨*Template matrix elements: public*⟩+≡

```
        public :: prc_template_me_t
```

⟨*Template matrix elements: types*⟩+≡
```
    type, extends (prc_core_t) :: prc_template_me_t
      real(default), dimension(:), allocatable :: par
     contains
     ⟨Template matrix elements: prc template ME: TBP⟩
    end type prc_template_me_t
```

The workspace associated to a `prc_template_me_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

⟨*Template matrix elements: types*⟩+≡
```
    type, extends (workspace_t) :: template_me_state_t
      logical :: new_kinematics = .true.
      real(default) :: alpha_qcd = -1
     contains
      procedure :: write => template_me_state_write
    end type template_me_state_t
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine template_me_state_write (object, unit)
      class(template_me_state_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u
      u = output_unit (unit)
      write (u, "(3x,A,L1)")  "Template ME state: new kinematics = ", &
          object%new_kinematics
    end subroutine template_me_state_write
```

Allocate the workspace with the above specific type.

⟨*Template matrix elements: prc template ME: TBP*⟩≡
```
    procedure :: allocate_workspace => prc_template_me_allocate_workspace
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine prc_template_me_allocate_workspace (object, tmp)
      class(prc_template_me_t), intent(in) :: object
      class(workspace_t), intent(inout), allocatable :: tmp
      allocate (template_me_state_t :: tmp)
    end subroutine prc_template_me_allocate_workspace
```

The following procedures are inherited from the base type as deferred, thus must be implemented. The corresponding unit tests are skipped here; the procedures are tested when called from the `processes` module.

Output: print just the ID of the associated matrix element. Then display any stored parameters.

⟨*Template matrix elements: prc template ME: TBP*⟩+≡
```
    procedure :: write => prc_template_me_write
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine prc_template_me_write (object, unit)
      class(prc_template_me_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u, i
      u = output_unit (unit)
      write (u, "(3x,A)", advance="no")  "Template process core:"
      if (object%data_known) then
         write (u, "(1x,A)")  char (object%data%id)
      else
         write (u, "(1x,A)")  "[undefined]"
      end if
      if (allocated (object%par)) then
         write (u, "(3x,A)")  "Parameter array:"
         do i = 1, size (object%par)
            write (u, "(5x,I0,1x,ES17.10)")  i, object%par(i)
         end do
      end if
    end subroutine prc_template_me_write
```

Temporarily store the parameter array inside the `prc_template_me` object, so
we can use it later during the actual initialization.

⟨*Template matrix elements: prc template ME: TBP*⟩+≡
```
    procedure :: set_parameters => prc_template_me_set_parameters
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine prc_template_me_set_parameters (prc_template_me, model)
      class(prc_template_me_t), intent(inout) :: prc_template_me
      type(model_t), intent(in), target, optional :: model
      if (present (model)) then
         if (allocated (prc_template_me%par))  deallocate (prc_template_me%par)
         call model_parameters_to_c_array (model, prc_template_me%par)
      end if
    end subroutine prc_template_me_set_parameters
```

To fully initialize the process core, we perform base initialization, then initialize
the external matrix element code.

This procedure overrides the `init` method of the base type, which we never-
theless can access via its binding `base_init`. When done, we have an allocated
driver. The driver will call the `init` procedure for the external matrix element,
and thus transfer the parameter set to where it finally belongs.

⟨*Template matrix elements: prc template ME: TBP*⟩+≡
```
    procedure :: init => prc_template_me_init
```

⟨*Template matrix elements: procedures*⟩+≡
```
    subroutine prc_template_me_init (object, def, lib, id, i_component)
      class(prc_template_me_t), intent(inout) :: object
      class(prc_core_def_t), intent(in), target :: def
      type(process_library_t), intent(in), target :: lib
      type(string_t), intent(in) :: id
      integer, intent(in) :: i_component
      call object%base_init (def, lib, id, i_component)
      call object%activate_parameters ()
```

```
      end subroutine prc_template_me_init
```

Activate the stored parameters by transferring them to the external matrix element.

⟨Template matrix elements: prc template ME: TBP⟩+≡
```
    procedure :: activate_parameters => prc_template_me_activate_parameters
```

⟨Template matrix elements: procedures⟩+≡
```
    subroutine prc_template_me_activate_parameters (object)
      class (prc_template_me_t), intent(inout) :: object
      if (allocated (object%driver)) then
         if (allocated (object%par)) then
            select type (driver => object%driver)
            type is (template_me_driver_t)
               if (associated (driver%init))  call driver%init (object%par)
            end select
         else
            call msg_bug ("prc_template_me_activate: parameter set is not allocated")
         end if
      else
         call msg_bug ("prc_template_me_activate: driver is not allocated")
      end if
    end subroutine prc_template_me_activate_parameters
```

The template ME process is an independent process which needs its own Monte Carlo parameter set for integration.

⟨Template matrix elements: prc template ME: TBP⟩+≡
```
    procedure :: needs_mcset => prc_template_me_needs_mcset
```

⟨Template matrix elements: procedures⟩+≡
```
    function prc_template_me_needs_mcset (object) result (flag)
      class(prc_template_me_t), intent(in) :: object
      logical :: flag
      flag = .true.
    end function prc_template_me_needs_mcset
```

There is only one term for this tree-level process.

⟨Template matrix elements: prc template ME: TBP⟩+≡
```
    procedure :: get_n_terms => prc_template_me_get_n_terms
```

⟨Template matrix elements: procedures⟩+≡
```
    function prc_template_me_get_n_terms (object) result (n)
      class(prc_template_me_t), intent(in) :: object
      integer :: n
      n = 1
    end function prc_template_me_get_n_terms
```

Tell whether a particular combination of flavor, helicity, color is allowed. Here we have to consult the matrix-element driver.

⟨Template matrix elements: prc template ME: TBP⟩+≡
```
    procedure :: is_allowed => prc_template_me_is_allowed
```

⟨*Template matrix elements: procedures*⟩+≡
```
   function prc_template_me_is_allowed (object, i_term, f, h, c) result (flag)
      class(prc_template_me_t), intent(in) :: object
      integer, intent(in) :: i_term, f, h, c
      logical :: flag
      logical(c_bool) :: cflag
      select type (driver => object%driver)
      type is (template_me_driver_t)
         call driver%is_allowed (f, h, c, cflag)
         flag = cflag
      end select
   end function prc_template_me_is_allowed
```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

We reset the `new_kinematics` flag, so that the next call to `compute_amplitude` will evaluate the matrix element.

⟨*Template matrix elements: prc template ME: TBP*⟩+≡
```
     procedure :: compute_hard_kinematics => &
         prc_template_me_compute_hard_kinematics
```

⟨*Template matrix elements: procedures*⟩+≡
```
     subroutine prc_template_me_compute_hard_kinematics &
         (object, p_seed, i_term, int_hard, tmp)
      class(prc_template_me_t), intent(in) :: object
      type(vector4_t), dimension(:), intent(in) :: p_seed
      integer, intent(in) :: i_term
      type(interaction_t), intent(inout) :: int_hard
      class(workspace_t), intent(inout), allocatable :: tmp
      call interaction_set_momenta (int_hard, p_seed)
      if (allocated (tmp)) then
         select type (tmp)
         type is (template_me_state_t);  tmp%new_kinematics = .true.
         end select
      end if
     end subroutine prc_template_me_compute_hard_kinematics
```

This procedure is not called for `prc_template_me_t`, just a placeholder.

⟨*Template matrix elements: prc template ME: TBP*⟩+≡
```
     procedure :: compute_eff_kinematics => &
         prc_template_me_compute_eff_kinematics
```

⟨*Template matrix elements: procedures*⟩+≡
```
     subroutine prc_template_me_compute_eff_kinematics &
         (object, i_term, int_hard, int_eff, tmp)
      class(prc_template_me_t), intent(in) :: object
      integer, intent(in) :: i_term
      type(interaction_t), intent(in) :: int_hard
      type(interaction_t), intent(inout) :: int_eff
      class(workspace_t), intent(inout), allocatable :: tmp
     end subroutine prc_template_me_compute_eff_kinematics
```

Recover the momenta within the hard interaction. For tree-level processes, this is a trivial copy of the incoming seed and outgoing effective momenta. The effective interaction is a pointer to the hard interaction, so the latter is ignored.

⟨*Template matrix elements: prc template ME: TBP*⟩+≡
```
  procedure :: recover_kinematics => prc_template_me_recover_kinematics
```

⟨*Template matrix elements: tests*⟩≡
```
  subroutine prc_template_me_recover_kinematics &
      (object, p_seed, int_hard, int_eff, tmp)
    class(prc_template_me_t), intent(in) :: object
    type(vector4_t), dimension(:), intent(inout) :: p_seed
    type(interaction_t), intent(inout) :: int_hard
    type(interaction_t), intent(inout) :: int_eff
    class(workspace_t), intent(inout), allocatable :: tmp
    integer :: n_in
    n_in = interaction_get_n_in (int_eff)
    call interaction_set_momenta (int_eff, p_seed(1:n_in), outgoing = .false.)
    p_seed(n_in+1:) = interaction_get_momenta (int_eff, outgoing = .true.)
  end subroutine prc_template_me_recover_kinematics
```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index `j` is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `tmp` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics` flag.

⟨*Template matrix elements: prc template ME: TBP*⟩+≡
```
  procedure :: compute_amplitude => prc_template_me_compute_amplitude
```

⟨*Template matrix elements: procedures*⟩+≡
```
  function prc_template_me_compute_amplitude &
      (object, j, p, f, h, c, fac_scale, ren_scale, tmp) result (amp)
    class(prc_template_me_t), intent(in) :: object
    integer, intent(in) :: j
    type(vector4_t), dimension(:), intent(in) :: p
    integer, intent(in) :: f, h, c
    real(default), intent(in) :: fac_scale, ren_scale
    class(workspace_t), intent(inout), allocatable, optional :: tmp
    complex(default) :: amp
    integer :: n_tot, i
    real(c_default_float), dimension(:,:), allocatable :: parray
    complex(c_default_complex) :: camp
    logical :: new_event
    select type (driver => object%driver)
    type is (template_me_driver_t)
      new_event = .true.

        end if
    end select
  end function prc_template_me_compute_amplitude
```

We do not overwrite the `prc_core_t` routine for α_s.

18.1.6 Test

This is the master for calling self-test procedures. There is a separate test for
testing O'MEGA diagram generation as this depends on a working analysis setup.

⟨*Template matrix elements: public*⟩+≡
```
    public :: prc_template_me_test
```

⟨*Template matrix elements: tests*⟩+≡
```
    subroutine prc_template_me_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
    ⟨Template matrix elements: execute tests⟩
  end subroutine prc_template_me_test
```

Generate, compile and load a simple process matrix element

The process is $e^+e^- \to \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize
the process, build the library, and compute a particular matrix element for
momenta of unit energy and right-angle scattering. The matrix element, as it
happens, is equal to e^2. (Note that are no conversion factors applied, so this
result is exact.)

For GNU make, `makeflags` is set to `-j1`. This eliminates a potential clash
with a `-j<n>` flag if this test is called from a parallel make.

⟨*Template matrix elements: execute tests*⟩≡
```
    call test (prc_template_me_1, "prc_template_me_1", &
        "build and load simple template process", &
        u, results)
```

18.2   `O'MEGA` Interface

The standard method for process computation with `WHIZARD` is the `O'MEGA`
matrix element generator.

   This section implements the interface to the code generator (via the makefile)
and the driver for the features provided by the `O'MEGA` matrix element.

⟨`prc_omega.f90`⟩≡
  ⟨*File header*⟩

```
  module prc_omega

18.2.1 Process definition

For the process definition we implement an extension of the `prc_core_def_t` abstract type.

⟨*Omega interface: public*⟩≡
```
public :: omega_def_t
```

⟨*Omega interface: types*⟩≡
```
type, extends (prc_core_def_t) :: omega_def_t
 contains
 ⟨Omega interface: omega def: TBP⟩
end type omega_def_t
```

⟨*Omega interface: omega def: TBP*⟩≡
```
procedure, nopass :: type_string => omega_def_type_string
```

⟨*Omega interface: procedures*⟩≡
```
function omega_def_type_string () result (string)
  type(string_t) :: string
  string = "omega"
end function omega_def_type_string
```

Initialization: allocate the writer for the O'MEGA matrix element. Also set any data for this process that the writer needs.

⟨*Omega interface: omega def: TBP*⟩+≡
```
procedure :: init => omega_def_init
```

⟨*Omega interface: procedures*⟩+≡
```
subroutine omega_def_init (object, model_name, prt_in, prt_out, &
    restrictions, openmp_support, report_progress, extra_options, &
    diags, diags_color)
  class(omega_def_t), intent(out) :: object
  type(string_t), intent(in) :: model_name
  type(string_t), dimension(:), intent(in) :: prt_in
  type(string_t), dimension(:), intent(in) :: prt_out
  type(string_t), intent(in), optional :: restrictions
  logical, intent(in), optional :: openmp_support
  logical, intent(in), optional :: report_progress
  logical, intent(in), optional :: diags, diags_color
  type(string_t), intent(in), optional :: extra_options
  allocate (omega_writer_t :: object%writer)
  select type (writer => object%writer)
  type is (omega_writer_t)
     call writer%init (model_name, prt_in, prt_out, &
          restrictions, openmp_support, report_progress, &
          extra_options, diags, diags_color)
  end select
end subroutine omega_def_init
```

Write/read process- and method-specific data.

⟨*Omega interface: omega def: TBP*⟩+≡
```
procedure :: write => omega_def_write
```

⟨*Omega interface: procedures*⟩+≡
```
subroutine omega_def_write (object, unit)
  class(omega_def_t), intent(in) :: object
  integer, intent(in) :: unit
  select type (writer => object%writer)
  type is (omega_writer_t)
     call writer%write (unit)
  end select
end subroutine omega_def_write
```

⟨*Omega interface: omega def: TBP*⟩+≡
```
procedure :: read => omega_def_read
```

⟨*Omega interface: procedures*⟩+≡
```
subroutine omega_def_read (object, unit)
  class(omega_def_t), intent(out) :: object
  integer, intent(in) :: unit
  call msg_bug ("O'Mega process definition: input not supported yet")
end subroutine omega_def_read
```

Allocate the driver for O'MEGAmatrix elements.
⟨*Omega interface: omega def: TBP*⟩+≡
```
procedure :: allocate_driver => omega_def_allocate_driver
```

⟨*Omega interface: procedures*⟩+≡
```
subroutine omega_def_allocate_driver (object, driver, basename)
  class(omega_def_t), intent(in) :: object
  class(prc_core_driver_t), intent(out), allocatable :: driver
  type(string_t), intent(in) :: basename
  allocate (omega_driver_t :: driver)
end subroutine omega_def_allocate_driver
```

We need code:
⟨*Omega interface: omega def: TBP*⟩+≡
```
procedure, nopass :: needs_code => omega_def_needs_code
```

⟨*Omega interface: procedures*⟩+≡
```
function omega_def_needs_code () result (flag)
  logical :: flag
  flag = .true.
end function omega_def_needs_code
```

These are the features that an O'MEGA matrix element provides.
⟨*Omega interface: omega def: TBP*⟩+≡
```
procedure, nopass :: get_features => omega_def_get_features
```

⟨*Omega interface: procedures*⟩+≡
```
subroutine omega_def_get_features (features)
  type(string_t), dimension(:), allocatable, intent(out) :: features
  allocate (features (6))
  features = [ &
       var_str ("init"), &
       var_str ("update_alpha_s"), &
```

```
              var_str ("reset_helicity_selection"), &
              var_str ("is_allowed"), &

     call lib_driver%get_fptr (pid, fid, fptr)
     call c_f_procpointer (fptr, proc_driver%get_amplitude)
  end select
end subroutine omega_def_connect
```

18.2.2   The `O'MEGA` writer

The `O'MEGA` writer is responsible for inserting the appropriate lines in the makefile that call `O'MEGA`, and for writing interfaces and wrappers.

⟨*Omega interface: types*⟩+≡
```
type, extends (prc_writer_f_module_t) :: omega_writer_t
  type(string_t) :: model_name
  type(string_t) :: process_mode
  type(string_t) :: process_string
  type(string_t) :: restrictions
  logical :: openmp_support = .false.
  logical :: report_progress = .false.
  logical :: diags = .false.
  logical :: diags_color = .false.
  type(string_t) :: extra_options
contains
```

⟨*Omega interface: omega writer: TBP*⟩
```
    end type omega_writer_t
```

The reported type is the same as for the `omega_def_t` type.

⟨*Omega interface: omega writer: TBP*⟩≡
```
    procedure, nopass :: type_name => omega_writer_type_name
```

⟨*Omega interface: procedures*⟩+≡
```
    function omega_writer_type_name () result (string)
      type(string_t) :: string
      string = "omega"
    end function omega_writer_type_name
```

Taking into account the prefix for `O'MEGA` module names.

⟨*Omega interface: omega writer: TBP*⟩+≡
```
    procedure, nopass :: get_module_name => omega_writer_get_module_name
```

⟨*Omega interface: procedures*⟩+≡
```
    function omega_writer_get_module_name (id) result (name)
      type(string_t) :: name
      type(string_t), intent(in) :: id
      name = "opr_" // id
    end function omega_writer_get_module_name
```

Output. This is called by `omega_def_write`.

⟨*Omega interface: omega writer: TBP*⟩+≡
```
    procedure :: write => omega_writer_write
```

⟨*Omega interface: procedures*⟩+≡
```
    subroutine omega_writer_write (object, unit)
      class(omega_writer_t), intent(in) :: object
      integer, intent(in) :: unit
      write (unit, "(5x,A,A)")  "Model name       = ", &
           '"' // char (object%model_name) // '"'
      write (unit, "(5x,A,A)")  "Mode string      = ", &
           '"' // char (object%process_mode) // '"'
      write (unit, "(5x,A,A)")  "Process string   = ", &
           '"' // char (object%process_string) // '"'

18.2.3 Driver

⟨Omega interface: types⟩+≡
```
type, extends (prc_core_driver_t) :: omega_driver_t
  procedure(init_t), nopass, pointer :: &
       init => null ()
  procedure(update_alpha_s_t), nopass, pointer :: &
       update_alpha_s => null ()
  procedure(reset_helicity_selection_t), nopass, pointer :: &
       reset_helicity_selection => null ()
  procedure(is_allowed_t), nopass, pointer :: &
       is_allowed => null ()
  procedure(new_event_t), nopass, pointer :: &
       new_event => null ()
  procedure(get_amplitude_t), nopass, pointer :: &
       get_amplitude => null ()
 contains
 ⟨Omega interface: omega driver: TBP⟩
end type omega_driver_t
```

The reported type is the same as for the `omega_def_t` type.

⟨Omega interface: omega driver: TBP⟩≡
```
procedure, nopass :: type_name => omega_driver_type_name
```

⟨Omega interface: procedures⟩+≡
```
function omega_driver_type_name () result (string)
  type(string_t) :: string
  string = "omega"
end function omega_driver_type_name
```

18.2.4 High-level process definition

This procedure wraps the details filling a process-component definition entry as appropriate for an `O'MEGA` matrix element.

NOTE: For calling the `import_component` method, we must explicitly address the `process_def_t` parent object. The natural way to call the method of the extended type triggers a bug in gfortran 4.6. The string array arguments `prt_in` and `prt_out` become corrupted and cause a segfault.

⟨Omega interface: public⟩+≡
```
public :: omega_make_process_component
```

⟨Omega interface: procedures⟩+≡
```
subroutine omega_make_process_component (entry, component_index, &
     model_name, prt_in, prt_out, restrictions, openmp_support, &
     report_progress, extra_options, diags, diags_color)
  class(process_def_entry_t), intent(inout) :: entry
  integer, intent(in) :: component_index
  type(string_t), intent(in) :: model_name
  type(string_t), dimension(:), intent(in) :: prt_in
  type(string_t), dimension(:), intent(in) :: prt_out
  type(string_t), intent(in), optional :: restrictions
  logical, intent(in), optional :: openmp_support
  logical, intent(in), optional :: report_progress
```

```
      logical, intent(in), optional :: diags, diags_color
      type(string_t), intent(in), optional :: extra_options
      class(prc_core_def_t), allocatable :: def
      allocate (omega_def_t :: def)
      select type (def)
      type is (omega_def_t)
         call def%init (model_name, prt_in, prt_out, &
              restrictions, openmp_support, report_progress, &
              extra_options, diags, diags_color)
      end select
      call entry%process_def_t%import_component (component_index, &
           n_out = size (prt_out), &
           prt_in  = new_prt_spec (prt_in), &
           prt_out = new_prt_spec (prt_out), &
           method = var_str ("omega"), &
           variant = def)
    end subroutine omega_make_process_component
```

18.2.5 The `prc_omega_t` wrapper

This is an instance of the generic `prc_core_t` object. It contains a pointer to the process definition (`omega_def_t`), a data component (`process_constants_t`), and the matrix-element driver (`omega_driver_t`).

⟨*Omega interface: public*⟩+≡
```
    public :: prc_omega_t
```

⟨*Omega interface: types*⟩+≡
```
    type, extends (prc_core_t) :: prc_omega_t
      real(default), dimension(:), allocatable :: par
      type(helicity_selection_t) :: helicity_selection
      type(qcd_t) :: qcd
     contains
     ⟨Omega interface: prc omega: TBP⟩
    end type prc_omega_t
```

The workspace associated to a `prc_omega_t` object contains a single flag. The flag is used to suppress re-evaluating the matrix element for each quantum-number combination, after the first amplitude belonging to a given kinematics has been computed.

We can also store the value of a running coupling once it has been calculated for an event. The default value is negative, which indicates an undefined value in this context.

⟨*Omega interface: types*⟩+≡
```
    type, extends (workspace_t) :: omega_state_t
      logical :: new_kinematics = .true.
      real(default) :: alpha_qcd = -1
     contains
       procedure :: write => omega_state_write
    end type omega_state_t
```

⟨*Omega interface: procedures*⟩+≡
```
    subroutine omega_state_write (object, unit)
      class(omega_state_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u
      u = output_unit (unit)
      write (u, "(3x,A,L1)")  "O'Mega state: new kinematics = ", &
           object%new_kinematics
    end subroutine omega_state_write
```

Allocate the workspace with the above specific type.

⟨*Omega interface: prc omega: TBP*⟩≡
```
    procedure :: allocate_workspace => prc_omega_allocate_workspace
```

⟨*Omega interface: procedures*⟩+≡
```
    subroutine prc_omega_allocate_workspace (object, tmp)
      class(prc_omega_t), intent(in) :: object
      class(workspace_t), intent(inout), allocatable :: tmp
      allocate (omega_state_t :: tmp)
    end subroutine prc_omega_allocate_workspace
```

The following procedures are inherited from the base type as deferred, thus must be implemented. The corresponding unit tests are skipped here; the procedures are tested when called from the `processes` module.

Output: print just the ID of the associated matrix element. Then display any stored parameters and the helicity selection data. (The latter are printed only if active.)

⟨*Omega interface: prc omega: TBP*⟩+≡
```
    procedure :: write => prc_omega_write
```

⟨*Omega interface: procedures*⟩+≡
```
    subroutine prc_omega_write (object, unit)
      class(prc_omega_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u, i
      u = output_unit (unit)
      write (u, "(3x,A)", advance="no")  "O'Mega process core:"
      if (object%data_known) then
         write (u, "(1x,A)")  char (object%data%id)
      else
         write (u, "(1x,A)")  "[undefined]"
      end if
      if (allocated (object%par)) then
         write (u, "(3x,A)")  "Parameter array:"
         do i = 1, size (object%par)
            write (u, "(5x,I0,1x,ES17.10)")  i, object%par(i)
         end do
      end if
      call object%helicity_selection%write (u)
      call object%qcd%write (u)
    end subroutine prc_omega_write
```

Temporarily store the parameter array inside the `prc_omega` object, so we can use it later during the actual initialization. Also store threshold and cutoff for helicity selection.

⟨*Omega interface: prc omega: TBP*⟩+≡
```
    procedure :: set_parameters => prc_omega_set_parameters
```

⟨*Omega interface: procedures*⟩+≡
```
    subroutine prc_omega_set_parameters (prc_omega, model, &
        helicity_selection, qcd, use_color_factors)
      class(prc_omega_t), intent(inout) :: prc_omega
      type(model_t), intent(in), target, optional :: model
      type(helicity_selection_t), intent(in), optional :: helicity_selection
      type(qcd_t), intent(in), optional :: qcd
      logical, intent(in), optional :: use_color_factors
      if (present (model)) then
         if (allocated (prc_omega%par))  deallocate (prc_omega%par)
         call model_parameters_to_c_array (model, prc_omega%par)
      end if
      if (present (helicity_selection)) then
         prc_omega%helicity_selection = helicity_selection
      end if
      if (present (qcd)) then
         prc_omega%qcd = qcd
      end if
      if (present (use_color_factors)) then
         prc_omega%use_color_factors = use_color_factors
      end if
    end subroutine prc_omega_set_parameters
```

To fully initialize the process core, we perform base initialization, then initialize the external matrix element code.

This procedure overrides the `init` method of the base type, which we nevertheless can access via its binding `base_init`. When done, we have an allocated driver. The driver will call the `init` procedure for the external matrix element, and thus transfer the parameter set to where it finally belongs.

If requested, we initialize the helicity selction counter.

⟨*Omega interface: prc omega: TBP*⟩+≡
```
    procedure :: init => prc_omega_init
```

⟨*Omega interface: procedures*⟩+≡
```
    subroutine prc_omega_init (object, def, lib, id, i_component)
      class(prc_omega_t), intent(inout) :: object
      class(prc_core_def_t), intent(in), target :: def
      type(process_library_t), intent(in), target :: lib
      type(string_t), intent(in) :: id
      integer, intent(in) :: i_component
      call object%base_init (def, lib, id, i_component)
      call object%activate_parameters ()
    end subroutine prc_omega_init
```

Activate the stored parameters by transferring them to the external matrix element. Also reset the helicity selection, if requested.

⟨*Omega interface: prc omega: TBP*⟩+≡

```
      procedure :: activate_parameters => prc_omega_activate_parameters
```

⟨*Omega interface: procedures*⟩+≡
```
    subroutine prc_omega_activate_parameters (object)
      class (prc_omega_t), intent(inout) :: object
      if (allocated (object%driver)) then
         if (allocated (object%par)) then
            select type (driver => object%driver)
            type is (omega_driver_t)
               if (associated (driver%init))  call driver%init (object%par)
            end select
         else
            call msg_bug ("prc_omega_activate: parameter set is not allocated")
         end if
         call object%reset_helicity_selection ()
      else
         call msg_bug ("prc_omega_activate: driver is not allocated")
      end if
    end subroutine prc_omega_activate_parameters
```

The `O'MEGA` process is an independent process which needs its own Monte Carlo parameter set for integration.

⟨*Omega interface: prc omega: TBP*⟩+≡
```
    procedure :: needs_mcset => prc_omega_needs_mcset
```

⟨*Omega interface: procedures*⟩+≡
```
    function prc_omega_needs_mcset (object) result (flag)
      class(prc_omega_t), intent(in) :: object
      logical :: flag
      flag = .true.
    end function prc_omega_needs_mcset
```

There is only one term for this tree-level process.

⟨*Omega interface: prc omega: TBP*⟩+≡
```
    procedure :: get_n_terms => prc_omega_get_n_terms
```

⟨*Omega interface: procedures*⟩+≡
```
    function prc_omega_get_n_terms (object) result (n)
      class(prc_omega_t), intent(in) :: object
      integer :: n
      n = 1
    end function prc_omega_get_n_terms
```

Tell whether a particular combination of flavor, helicity, color is allowed. Here we have to consult the matrix-element driver.

⟨*Omega interface: prc omega: TBP*⟩+≡
```
    procedure :: is_allowed => prc_omega_is_allowed
```

⟨*Omega interface: procedures*⟩+≡
```
  function prc_omega_is_allowed (object, i_term, f, h, c) result (flag)
    class(prc_omega_t), intent(in) :: object
    integer, intent(in) :: i_term, f, h, c
    logical :: flag
    logical(c_bool) :: cflag
```

2498

```
        select type (driver => object%driver)
        type is (omega_driver_t)
           call driver%is_allowed (f, h, c, cflag)
           flag = cflag
        end select
     end function prc_omega_is_allowed
```

Transfer the generated momenta directly to the hard interaction in the (only) term. We assume that everything has been set up correctly, so the array fits.

We reset the `new_kinematics` flag, so that the next call to `compute_amplitude` will evaluate the matrix element.

⟨*Omega interface: prc omega: TBP*⟩+≡
```
     procedure :: compute_hard_kinematics => prc_omega_compute_hard_kinematics
```

⟨*Omega interface: procedures*⟩+≡
```
     subroutine prc_omega_compute_hard_kinematics &
         (object, p_seed, i_term, int_hard, tmp)
       class(prc_omega_t), intent(in) :: object
       type(vector4_t), dimension(:), intent(in) :: p_seed
       integer, intent(in) :: i_term
       type(interaction_t), intent(inout) :: int_hard
       class(workspace_t), intent(inout), allocatable :: tmp
       call interaction_set_momenta (int_hard, p_seed)
       if (allocated (tmp)) then
          select type (tmp)
          type is (omega_state_t);  tmp%new_kinematics = .true.
          end select
       end if
     end subroutine prc_omega_compute_hard_kinematics
```

This procedure is not called for `prc_omega_t`, just a placeholder.

⟨*Omega interface: prc omega: TBP*⟩+≡
```
     procedure :: compute_eff_kinematics => prc_omega_compute_eff_kinematics
```

⟨*Omega interface: procedures*⟩+≡
```
     subroutine prc_omega_compute_eff_kinematics &
         (object, i_term, int_hard, int_eff, tmp)
       class(prc_omega_t), intent(in) :: object
       integer, intent(in) :: i_term
       type(interaction_t), intent(in) :: int_hard
       type(interaction_t), intent(inout) :: int_eff
       class(workspace_t), intent(inout), allocatable :: tmp
     end subroutine prc_omega_compute_eff_kinematics
```

Recover the momenta within the hard interaction. For tree-level processes, this is a trivial copy of the incoming seed and outgoing effective momenta. The effective interaction is a pointer to the hard interaction, so the latter is ignored.

⟨*Omega interface: prc omega: TBP*⟩+≡
```
     procedure :: recover_kinematics => prc_omega_recover_kinematics
```

⟨*Omega interface: tests*⟩≡
```
     subroutine prc_omega_recover_kinematics &
         (object, p_seed, int_hard, int_eff, tmp)
```

```
        class(prc_omega_t), intent(in) :: object
        type(vector4_t), dimension(:), intent(inout) :: p_seed
        type(interaction_t), intent(inout) :: int_hard
        type(interaction_t), intent(inout) :: int_eff
        class(workspace_t), intent(inout), allocatable :: tmp
        integer :: n_in
        n_in = interaction_get_n_in (int_eff)
        call interaction_set_momenta (int_eff, p_seed(1:n_in), outgoing = .false.)
        p_seed(n_in+1:) = interaction_get_momenta (int_eff, outgoing = .true.)
      end subroutine prc_omega_recover_kinematics
```

Reset the helicity selection counters and start counting zero helicities. We assume that the `helicity_selection` object is allocated. Otherwise, reset and switch off helicity counting.

In the test routine, the driver is allocated but the driver methods are not. Therefore, guard against a disassociated method.

⟨*Omega interface: prc omega: TBP*⟩+≡
```
      procedure :: reset_helicity_selection => prc_omega_reset_helicity_selection
```

⟨*Omega interface: procedures*⟩+≡
```
      subroutine prc_omega_reset_helicity_selection (object)
        class(prc_omega_t), intent(inout) :: object
        select type (driver => object%driver)
        type is (omega_driver_t)
           if (associated (driver%reset_helicity_selection)) then
              if (object%helicity_selection%active) then
                 call driver%reset_helicity_selection &
                      (real (object%helicity_selection%threshold, &

        end select
      end subroutine prc_omega_reset_helicity_selection
```

Compute the amplitude. For the tree-level process, we can ignore the scale settings. The term index `j` is also irrelevant.

We first call `new_event` for the given momenta (which we must unpack), then retrieve the amplitude value for the given quantum numbers.

If the `tmp` status flag is present, we can make sure that we call `new_event` only once for a given kinematics. After the first call, we unset the `new_kinematics` flag.

The `is_allowed` query is not redundant, since the status may change during the run if helicities are switched off.

  integer, intent(in) :: u
  type(test_results_t), intent(inout) :: results
  ⟨Omega interface: execute diags tests⟩
end subroutine prc_omega_diags_test
```

Generate, compile and load a simple process matrix element

The process is $e^+e^- \rightarrow \mu^+\mu^-$ for vanishing masses and $e = 0.3$. We initialize the process, build the library, and compute a particular matrix element for momenta of unit energy and right-angle scattering. The matrix element, as it happens, is equal to e^2. (Note that are no conversion factors applied, so this result is exact.)

2502

For GNU make, makeflags is set to -j1. This eliminates a potential clash with a -j<n> flag if this test is called from a parallel make.

Check `prc_omega_t` wrapper and options

The process is $e^-e^+ \to e^-e^+$ for vanishing masses and $e = 0.3$. We build the library using the high-level procedure `omega_make_process_component` and the "black box" `prc_omega_t` object. Two variants with different settings for restrictions and OpenMP.

For `GNU make`, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

⟨*Omega interface: execute tests*⟩+≡

QCD coupling

The process is $u\bar{u} \to d\bar{d}$ for vanishing masses. We compute the amplitude for a fixed configuration once, then reset α_s, then compute again.

For `GNU make`, `makeflags` is set to `-j1`. This eliminates a potential clash with a `-j<n>` flag if this test is called from a parallel make.

Chapter 19

Event I/O

In this chapter we provide a generic handler for event I/O and the various implementations: raw, HepMC, Les Houches, etc.

19.1 Event Sample Data

We define a simple and transparent container for (meta)data that are associated with an event sample.

⟨eio_data.f90⟩≡
  ⟨*File header*⟩

  module eio_data

    use kinds !NODEP!
  ⟨*Use file utils*⟩
  ⟨*Use strings*⟩
    use diagnostics !NODEP!
    use unit_tests

    use events

  ⟨*EIO data: public*⟩

  ⟨*EIO data: types*⟩

  contains

  ⟨*EIO data: procedures*⟩

  ⟨*EIO data: tests*⟩

  end module eio_data

19.1.1 Event Sample Data

These are data that apply to an event sample as a whole. They are given in an easily portable form (no fancy structure) and are used for initializing event

formats.

There are two MD5 sums here. `md5sum_proc` depends only on the definition of the contributing processes. A sample with matching checksum can be rescanned with modified model parameters, beam structure etc, to recalculate observables. `md5sum_config` includes all relevant data. Rescanning a sample with matching checksum will produce identical observables. (A third checksum might be added which depends on the event sample itself. This is not needed, so far.)

If alternate weights are part of the event sample (`n_alt` nonzero), there is a configuration MD5 sum for each of them.

⟨*EIO data: public*⟩≡
```
    public :: event_sample_data_t
```

⟨*EIO data: types*⟩≡
```
    type :: event_sample_data_t
       character(32) :: md5sum_prc = ""
       character(32) :: md5sum_cfg = ""
       logical :: unweighted = .true.
       logical :: negative_weights = .false.
       integer :: norm_mode = NORM_UNDEFINED
       integer :: n_beam = 0
       integer, dimension(2) :: pdg_beam = 0
       real(default), dimension(2) :: energy_beam = 0
       integer :: n_proc = 0
       integer :: n_evt = 0
       integer :: split_n_evt = 0
       integer :: split_index = 0
       real(default) :: total_cross_section = 0
       integer, dimension(:), allocatable :: proc_num_id
       integer :: n_alt = 0
       character(32), dimension(:), allocatable :: md5sum_alt
       real(default), dimension(:), allocatable :: cross_section
       real(default), dimension(:), allocatable :: error
     contains
     ⟨EIO data: event sample data: TBP⟩
    end type event_sample_data_t
```

Initialize: allocate for the number of processes

⟨*EIO data: event sample data: TBP*⟩≡
```
    procedure :: init => event_sample_data_init
```

⟨*EIO data: procedures*⟩≡
```
    subroutine event_sample_data_init (data, n_proc, n_alt)
      class(event_sample_data_t), intent(out) :: data
      integer, intent(in) :: n_proc
      integer, intent(in), optional :: n_alt
      data%n_proc = n_proc
      allocate (data%proc_num_id (n_proc), source = 0)
      allocate (data%cross_section (n_proc), source = 0._default)
      allocate (data%error (n_proc), source = 0._default)
      if (present (n_alt)) then
         data%n_alt = n_alt
         allocate (data%md5sum_alt (n_alt))
```

```
        data%md5sum_alt = ""
      end if
    end subroutine event_sample_data_init
```

    end subroutine eio_data_2
```

19.2   Abstract I/O Handler

This module defines an abstract object for event I/O and the associated methods.

There are `output` and `input` methods which write or read a single event from/to the I/O stream, respectively. The I/O stream itself may be a file, a common block, or an externally linked structure, depending on the concrete implementation.

A `write` method prints the current content of the implementation-dependent event record in human-readable form.

The `init_in`/`init_out` and `final` prepare and finalize the I/O stream, respectively. There is also a `switch_inout` method which turns an input stream into an output stream where events can be appended.

Optionally, output files can be split in chunks of well-defined size. The `split_out` method takes care of this.

⟨`eio_base.f90`⟩≡

  ⟨*File header*⟩

  `module eio_base`

    `use kinds !NODEP!`
  ⟨*Use file utils*⟩
  ⟨*Use strings*⟩
    `use diagnostics !NODEP!`
    `use unit_tests`

    `use lorentz !NODEP!`
    `use models`
    `use particles`
    `use beams`
    `use processes`
    `use events`
    `use eio_data`

  ⟨*Standard module head*⟩

  ⟨*EIO base: public*⟩

  ⟨*EIO base: types*⟩

  ⟨*EIO base: interfaces*⟩

  ⟨*EIO base: test types*⟩

  `contains`

  ⟨*EIO base: procedures*⟩

  ⟨*EIO base: tests*⟩

  `end module eio_base`

19.2.1 Process pointer

For handling multiple processes, we need an array of process pointers. This requires a wrapper:

⟨*EIO base: public*⟩≡
    `public :: process_ptr_t`

⟨*EIO base: types*⟩≡
    `type :: process_ptr_t`
      `type(process_t), pointer :: ptr => null ()`
    `end type process_ptr_t`

19.2.2 Type

We can assume that most implementations will need the file extension as a fixed string and, if they support file splitting, the current file index.

⟨*EIO base: public*⟩+≡
```
    public :: eio_t
```

⟨*EIO base: types*⟩+≡
```
    type, abstract :: eio_t
       type(string_t) :: sample
       type(string_t) :: extension
       type(string_t) :: filename
       logical :: split = .false.
       integer :: split_n_evt = 0
       integer :: split_index = 0
     contains
     ⟨EIO base: eio: TBP⟩
     end type eio_t
```

Write to screen. If possible, this should display the contents of the current event, i.e., the last one that was written or read.

⟨*EIO base: eio: TBP*⟩≡
```
    procedure (eio_write), deferred :: write
```

⟨*EIO base: interfaces*⟩≡
```
    abstract interface
       subroutine eio_write (object, unit)
         import
         class(eio_t), intent(in) :: object
         integer, intent(in), optional :: unit
       end subroutine eio_write
    end interface
```

Finalize. This should write/read footer data and close input/output channels.

⟨*EIO base: eio: TBP*⟩+≡
```
    procedure (eio_final), deferred :: final
```

⟨*EIO base: interfaces*⟩+≡
```
    abstract interface
       subroutine eio_final (object)
         import
         class(eio_t), intent(inout) :: object
       end subroutine eio_final
    end interface
```

Determine splitting parameters from the event sample data.

⟨*EIO base: eio: TBP*⟩+≡
```
    procedure :: set_splitting => eio_set_splitting
```

⟨*EIO base: procedures*⟩≡
```
    subroutine eio_set_splitting (eio, data)
      class(eio_t), intent(inout) :: eio
      type(event_sample_data_t), intent(in) :: data
      eio%split = data%split_n_evt > 0
```

```
         if (eio%split) then
            eio%split_n_evt = data%split_n_evt
            eio%split_index = data%split_index
         end if
      end subroutine eio_set_splitting
```

Generate a filename, taking a possible split index into account.

⟨*EIO base: eio: TBP*⟩+≡
```
      procedure :: set_filename => eio_set_filename
```

⟨*EIO base: procedures*⟩+≡
```
      subroutine eio_set_filename (eio)
        class(eio_t), intent(inout) :: eio
        character(32) :: buffer
        if (eio%split) then
           write (buffer, "(I0,'.')")  eio%split_index
           eio%filename = eio%sample // "." // trim (buffer) // eio%extension
        else
           eio%filename = eio%sample // "." // eio%extension
        end if
      end subroutine eio_set_filename
```

Initialize for output. We provide process pointers. This should open an event file if appropriate and write header data. Some methods may require event sample data.

⟨*EIO base: eio: TBP*⟩+≡
```
      procedure (eio_init_out), deferred :: init_out
```

⟨*EIO base: interfaces*⟩+≡
```
      abstract interface
         subroutine eio_init_out (eio, sample, process_ptr, data, success)
           import
           class(eio_t), intent(inout) :: eio
           type(string_t), intent(in) :: sample
           type(process_ptr_t), dimension(:), intent(in) :: process_ptr
           type(event_sample_data_t), intent(in), optional :: data
           logical, intent(out), optional :: success
         end subroutine eio_init_out
      end interface
```

Initialize for input. We provide process names. This should open an event file if appropriate and read header data. The `md5sum` can be used to check the integrity of the configuration, it it provides a checksum to compare with. In case the extension has changed the extension is also given as an argument.

The `data` argument is `intent(inout)`: we may read part of it and keep other parts and/or check them against the data in the file.

⟨*EIO base: eio: TBP*⟩+≡
```
      procedure (eio_init_in), deferred :: init_in
```

⟨*EIO base: interfaces*⟩+≡
```
      abstract interface
         subroutine eio_init_in (eio, sample, process_ptr, data, success, extension)
           import
```

2531

```
        class(eio_t), intent(inout) :: eio
        type(string_t), intent(in) :: sample
        type(string_t), intent(in), optional :: extension
        type(process_ptr_t), dimension(:), intent(in) :: process_ptr
        type(event_sample_data_t), intent(inout), optional :: data
        logical, intent(out), optional :: success
      end subroutine eio_init_in
    end interface
```

Re-initialize for output. This should change the status of any event file from
input to output and position it for appending new events.

⟨*EIO base: eio: TBP*⟩+≡
```
    procedure (eio_switch_inout), deferred :: switch_inout
```

⟨*EIO base: interfaces*⟩+≡
```
    abstract interface
      subroutine eio_switch_inout (eio, success)
        import
        class(eio_t), intent(inout) :: eio
        logical, intent(out), optional :: success
      end subroutine eio_switch_inout
    end interface
```

This is similar: split the output, i.e., close the current file and open a new
one. The default implementation does nothing. For the feature to work, an
implementation must override this.

⟨*EIO base: eio: TBP*⟩+≡
```
    procedure :: split_out => eio_split_out
```

⟨*EIO base: procedures*⟩+≡
```
    subroutine eio_split_out (eio)
      class(eio_t), intent(inout) :: eio
    end subroutine eio_split_out
```

Output an event. All data can be taken from the `event` record. The index `i_prc`
identifies the process among the processes that are contained in the current
sample. The `reading` flag, if present, indicates that the event was read from
file, not generated.

⟨*EIO base: eio: TBP*⟩+≡
```
    procedure (eio_output), deferred :: output
```

⟨*EIO base: interfaces*⟩+≡
```
    abstract interface
      subroutine eio_output (eio, event, i_prc, reading)
        import
        class(eio_t), intent(inout) :: eio
        type(event_t), intent(in), target :: event
        integer, intent(in) :: i_prc
        logical, intent(in), optional :: reading
      end subroutine eio_output
    end interface
```

Input an event. This should fill all event data that cannot be inferred from the associated process.

The input is broken down into two parts. First we read the `i_prc` index. So we know which process to expect in the subsequent event. If we have reached end of file, we also will know. Then, we read the event itself.

The parameter `iostat` is supposed to be set as the Fortran standard requires, negative for EOF and positive for error.

⟨*EIO base: eio: TBP*⟩+≡
```
    procedure (eio_input_i_prc), deferred :: input_i_prc
    procedure (eio_input_event), deferred :: input_event
```

⟨*EIO base: interfaces*⟩+≡
```
    abstract interface
       subroutine eio_input_i_prc (eio, i_prc, iostat)
         import
         class(eio_t), intent(inout) :: eio
         integer, intent(out) :: i_prc
         integer, intent(out) :: iostat
       end subroutine eio_input_i_prc
    end interface

    abstract interface
       subroutine eio_input_event (eio, event, iostat)
         import
         class(eio_t), intent(inout) :: eio
         type(event_t), intent(inout), target :: event
         integer, intent(out) :: iostat
       end subroutine eio_input_event
    end interface
```

19.2.3 Unit tests

⟨*EIO base: public*⟩+≡
```
    public :: eio_base_test
```

⟨*EIO base: tests*⟩≡
```
    subroutine eio_base_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
    ⟨EIO base: execute tests⟩
    end subroutine eio_base_test
```

Test type for event I/O

The contents simulate the contents of an external file. We have the `sample` string as the file name, `sqrts` and the array of `process_id`s as metadata, and the array of momenta `event_p` as the list of events. The second index is the event index. The `event_i` component is the pointer to the current event, `event_n` is the total number of stored events.

⟨*EIO base: test types*⟩≡
```
    type, extends (eio_t) :: eio_test_t
```

2533

```
      real(default) :: sqrts
      type(string_t) :: process_id
      integer :: event_n = 0
      integer :: event_i = 0
      integer :: i_prc = 0
      type(vector4_t), dimension(:,:), allocatable :: event_p
    contains
    ⟨EIO base: eio test: TBP⟩
  end type eio_test_t
```

Write to screen. Pretend that this is an actual event format.

⟨*EIO base: eio test: TBP*⟩≡
```
    procedure :: write => eio_test_write
```

⟨*EIO base: procedures*⟩+≡
```
    subroutine eio_test_write (object, unit)
      class(eio_test_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u, i
      u = output_unit (unit)
      write (u, "(1x,A)")  "Test event stream"
      write (u, "(3x,A,A,A)")  "Process ID  = '", char (object%process_id), "'"
      write (u, "(3x,A,ES19.12)")  "sqrts       = ", object%sqrts
      if (object%event_i /= 0) then
          write (u, "(1x,A,I0,A)")  "Event #", object%event_i, ":"
          do i = 1, size (object%event_p, 1)
             call vector4_write (object%event_p(i, object%event_i), u)
          end do
      end if
    end subroutine eio_test_write
```

Finalizer. For the test case, we just reset the event count, but keep the stored "events". For the real implementations, the events would be stored on an external medium, so we would delete the object contents.

⟨*EIO base: eio test: TBP*⟩+≡
```
    procedure :: final => eio_test_final
```

⟨*EIO base: procedures*⟩+≡
```
    subroutine eio_test_final (object)
      class(eio_test_t), intent(inout) :: object
      object%event_i = 0
    end subroutine eio_test_final
```

Initialization: We store the process IDs and the energy from the beam-data object. We also allocate the momenta (i.e., the simulated event record) for a fixed maximum size of 10 events, 2 momenta each. There is only a single process.

⟨*EIO base: eio test: TBP*⟩+≡
```
    procedure :: init_out => eio_test_init_out
```

⟨*EIO base: procedures*⟩+≡
```
    subroutine eio_test_init_out (eio, sample, process_ptr, data, success)
      class(eio_test_t), intent(inout) :: eio
```

```
    type(string_t), intent(in) :: sample
    type(process_ptr_t), dimension(:), intent(in) :: process_ptr
    type(event_sample_data_t), intent(in), optional :: data
    logical, intent(out), optional :: success
    type(beam_data_t), pointer :: beam_data
    eio%sample = sample
    eio%process_id = process_ptr(1)%ptr%get_id ()
    beam_data => process_ptr(1)%ptr%get_beam_data_ptr ()
    eio%sqrts = beam_data_get_sqrts (beam_data)
    eio%event_n = 0
    eio%event_i = 0
    allocate (eio%event_p (2, 10))
    if (present (success))  success = .true.
  end subroutine eio_test_init_out
```

Initialization for input. Nothing to do for the test type.

⟨*EIO base: eio test: TBP*⟩+≡
```
    procedure :: init_in => eio_test_init_in
```

⟨*EIO base: procedures*⟩+≡
```
    subroutine eio_test_init_in &
        (eio, sample, process_ptr, data, success, extension)
      class(eio_test_t), intent(inout) :: eio
      type(string_t), intent(in) :: sample
      type(string_t), intent(in), optional :: extension
      type(process_ptr_t), dimension(:), intent(in) :: process_ptr
      type(event_sample_data_t), intent(inout), optional :: data
      logical, intent(out), optional :: success
      if (present (success))  success = .true.
    end subroutine eio_test_init_in
```

Switch from output to input. Again, nothing to do for the test type.

⟨*EIO base: eio test: TBP*⟩+≡
```
    procedure :: switch_inout => eio_test_switch_inout
```

⟨*EIO base: procedures*⟩+≡
```
    subroutine eio_test_switch_inout (eio, success)
      class(eio_test_t), intent(inout) :: eio
      logical, intent(out), optional :: success
      if (present (success))  success = .true.
    end subroutine eio_test_switch_inout
```

Output. Increment the event counter and store the momenta of the current event.

⟨*EIO base: eio test: TBP*⟩+≡
```
    procedure :: output => eio_test_output
```

⟨*EIO base: procedures*⟩+≡
```
    subroutine eio_test_output (eio, event, i_prc, reading)
      class(eio_test_t), intent(inout) :: eio
      type(event_t), intent(in), target :: event
      logical, intent(in), optional :: reading
      integer, intent(in) :: i_prc
```

```
      type(particle_set_t), pointer :: pset
      type(particle_t) :: prt
      eio%event_n = eio%event_n + 1
      eio%event_i = eio%event_n
      eio%i_prc = i_prc
      pset => event%get_particle_set_ptr ()
      prt = particle_set_get_particle (pset, 3)
      eio%event_p(1, eio%event_i) = particle_get_momentum (prt)
      prt = particle_set_get_particle (pset, 4)
      eio%event_p(2, eio%event_i) = particle_get_momentum (prt)
    end subroutine eio_test_output
```

Input. Increment the event counter and retrieve the momenta of the current event. For the test case, we do not actually modify the current event.

⟨*EIO base: eio test: TBP*⟩+≡
```
    procedure :: input_i_prc => eio_test_input_i_prc
    procedure :: input_event => eio_test_input_event
```

⟨*EIO base: procedures*⟩+≡
```
    subroutine eio_test_input_i_prc (eio, i_prc, iostat)
      class(eio_test_t), intent(inout) :: eio
      integer, intent(out) :: i_prc
      integer, intent(out) :: iostat
      i_prc = eio%i_prc
      iostat = 0
    end subroutine eio_test_input_i_prc

    subroutine eio_test_input_event (eio, event, iostat)
      class(eio_test_t), intent(inout) :: eio
      type(event_t), intent(inout), target :: event
      integer, intent(out) :: iostat
      eio%event_i = eio%event_i + 1
      iostat = 0
    end subroutine eio_test_input_event
```

Test I/O methods

We test the implementation of all I/O methods using the `eio_test_t` type.

```

Output an event. Write first the event indices, then weight and squared matrix
element, then the particle set.

We always write the particle set of the hard process. (Note: this should be
reconsidered.) We do make a physical copy.

On output, we write the `prc` values for weight and sqme, since these are
the values just computed. On input, we store the values as `ref` values. The
caller can then decide whether to recompute values and thus obtain distinct `prc`
values, or just accept them.

    contains
    ⟨EIO checkpoints: eio checkpoints: TBP⟩
    end type eio_checkpoints_t
```

19.4.2   Specific Methods

Set parameters that are specifically used with LHEF.

⟨*EIO checkpoints: eio checkpoints: TBP*⟩≡
```
    procedure :: set_parameters => eio_checkpoints_set_parameters
```

⟨*EIO checkpoints: procedures*⟩≡
```
    subroutine eio_checkpoints_set_parameters (eio, checkpoint, blank)
      class(eio_checkpoints_t), intent(inout) :: eio
      integer, intent(in) :: checkpoint
      logical, intent(in), optional :: blank
      eio%val = checkpoint
      if (present (blank))  eio%blank = blank
    end subroutine eio_checkpoints_set_parameters
```

19.4.3   Common Methods

Output. This is not the actual event format, but a readable account of the current status.

⟨*EIO checkpoints: eio checkpoints: TBP*⟩+≡
```
    procedure :: write => eio_checkpoints_write
```

⟨*EIO checkpoints: procedures*⟩+≡
```
    subroutine eio_checkpoints_write (object, unit)
      class(eio_checkpoints_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u
      u = output_unit (unit)
      if (object%active) then
        write (u, "(1x,A)")  "Event-sample checkpoints:  active"
        write (u, "(3x,A,I0)")  "interval  = ", object%val
        write (u, "(3x,A,I0)")  "n_events  = ", object%n_events
        write (u, "(3x,A,I0)")  "n_read    = ", object%n_read
        write (u, "(3x,A,I0)")  "n_current = ", object%i_evt
        write (u, "(3x,A,L1)")  "blanking  = ", object%blank
        call object%timer%write (u)
      else
        write (u, "(1x,A)")  "Event-sample checkpoints:  off"
      end if
    end subroutine eio_checkpoints_write
```

Finalizer: trivial.

```

19.5 HEP Common Blocks

Long ago, to transfer data between programs one had to set up a common
block and link both programs as libraries to the main executable. The HEP
community standardizes several of those common blocks.

The modern way of data exchange uses data files with standard formats.
However, the LHEF standard data format derives from a common block (actu-
ally, two).

WHIZARD used to support those common blocks, and LHEF was implemented
via writing/reading blocks. We still keep this convention, but intend to eliminate
common blocks (or any other static storage) from the workflow in the future.
This will gain flexibility towards concurrent running of program images.

We encapsulate everything here in a module. The module holds the variables
which are part of the common block.

Note: This code is taken essentially unchanged from WHIZARD 2.1 and does
not (yet) provide unit tests.

contains
```

⟨*HEP common: procedures*⟩

```
end module hep_common
```

19.5.1 Event characteristics

The maximal number of particles in an event record.

⟨*HEP common: parameters*⟩≡
```
    integer, parameter :: MAXNUP = 500
```

The number of particles in this event.

⟨*HEP common: variables*⟩≡
```
    integer :: NUP
```

The process ID for this event.

⟨*HEP common: variables*⟩+≡
```
    integer :: IDPRUP
```

The weight of this event (± 1 for unweighted events).

⟨*HEP common: variables*⟩+≡
```
    double precision :: XWGTUP
```

The factorization scale that is used for PDF calculation (-1 if undefined).

⟨*HEP common: variables*⟩+≡
```
    double precision :: SCALUP
```

The QED and QCD couplings α used for this event (-1 if undefined).

⟨*HEP common: variables*⟩+≡
```
    double precision :: AQEDUP
    double precision :: AQCDUP
```

19.5.2 Particle characteristics

The PDG code:

⟨*HEP common: variables*⟩+≡
```
    integer, dimension(MAXNUP) :: IDUP
```

The status code. Incoming: -1, outgoing: $+1$. Intermediate t-channel propagator: -2 (currently not used by WHIZARD). Intermediate resonance whose mass should be preserved: 2. Intermediate resonance for documentation: 3 (currently not used). Beam particles: -9.

⟨*HEP common: variables*⟩+≡
```
    integer, dimension(MAXNUP) :: ISTUP
```

Index of first and last mother.

⟨*HEP common: variables*⟩+≡
```
    integer, dimension(2,MAXNUP) :: MOTHUP
```

Color line index of the color and anticolor entry for the particle. The standard recommends using large numbers; we start from MAXNUP+1.

⟨*HEP common: variables*⟩+≡
```
    integer, dimension(2,MAXNUP) :: ICOLUP
```

Momentum, energy, and invariant mass: (p_x, p_y, p_z, E, M). For space-like particles, M is the negative square root of the absolute value of the invariant mass.

⟨*HEP common: variables*⟩+≡
```
    double precision, dimension(5,MAXNUP) :: PUP
```

Invariant lifetime (distance) from production to decay in mm.

⟨*HEP common: variables*⟩+≡
```
    double precision, dimension(MAXNUP) :: VTIMUP
```

Cosine of the angle between the spin-vector and a particle and the 3-momentum of its mother, given in the lab frame. If undefined/unpolarized: 9.

⟨*HEP common: variables*⟩+≡
```
    double precision, dimension(MAXNUP) :: SPINUP
```

19.5.3   The HEPRUP common block

This common block is filled once per run.

Run characteristics

The maximal number of different processes.

⟨*HEP common: parameters*⟩+≡
```
    integer, parameter :: MAXPUP = 100
```

The beam PDG codes.

⟨*HEP common: variables*⟩+≡
```
    integer, dimension(2) :: IDBMUP
```

The beam energies in GeV.

⟨*HEP common: variables*⟩+≡
```
    double precision, dimension(2) :: EBMUP
```

The PDF group and set for the two beams. (Undefined: use −1; LHAPDF: use group = 0).

⟨*HEP common: variables*⟩+≡
```
    integer, dimension(2) :: PDFGUP
    integer, dimension(2) :: PDFSUP
```

The (re)weighting model. 1: events are weighted, the shower generator (SHG) selects processes according to the maximum weight (in pb) and unweights events. 2: events are weighted, the SHG selects processes according to their cross section (in pb) and unweights events. 3: events are unweighted and simply run through the SHG. 4: events are weighted, and the SHG keeps the weight. Negative numbers: negative weights are allowed (and are reweighted to ±1 by the SHG, if allowed).

WHIZARD only supports modes 3 and 4, as the SHG is not given control over process selection. This is consistent with writing events to file, for offline showering.

⟨*HEP common: variables*⟩+≡
```
integer :: IDWTUP
```

The number of different processes.

⟨*HEP common: variables*⟩+≡
```
integer :: NPRUP
```

Process characteristics

Cross section and error in pb. (Cross section is needed only for `IDWTUP` = 2, so here both values are given for informational purposes only.)

⟨*HEP common: variables*⟩+≡
```
double precision, dimension(MAXPUP) :: XSECUP
double precision, dimension(MAXPUP) :: XERRUP
```

Maximum weight, i.e., the maximum value that `XWGTUP` can take. Also unused for the supported weighting models. It is ±1 for unweighted events.

⟨*HEP common: variables*⟩+≡
```
double precision, dimension(MAXPUP) :: XMAXUP
```

Internal ID of the selected process, matches `IDPRUP` below.

⟨*HEP common: variables*⟩+≡
```
integer, dimension(MAXPUP) :: LPRUP
```

The common block

⟨*HEP common: common blocks*⟩≡
```
common /HEPRUP/ &
     IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP, &
     XSECUP, XERRUP, XMAXUP, LPRUP
save /HEPRUP/
```

Fill the run characteristics of the common block. The initialization sets the beam properties, number of processes, and weighting model.

⟨*HEP common: public*⟩≡
```
public :: heprup_init
```

⟨*HEP common: procedures*⟩≡
```
subroutine heprup_init &
     (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)
  integer, dimension(2), intent(in) :: beam_pdg
  real(default), dimension(2), intent(in) :: beam_energy
  integer, intent(in) :: n_processes
  logical, intent(in) :: unweighted
  logical, intent(in) :: negative_weights
  IDBMUP = beam_pdg
  EBMUP = beam_energy
  PDFGUP = -1
  PDFSUP = -1
  if (unweighted) then
     IDWTUP = 3
```

```
      else
         IDWTUP = 4
      end if
      if (negative_weights)  IDWTUP = - IDWTUP
      NPRUP = n_processes
   end subroutine heprup_init
```

Extract parameters from the common block. We leave it to the caller to specify which parameters it actually needs.

PDFGUP and PDFSUP are not extracted. IDWTUP=1,2 are not supported by WHIZARD, but correspond to weighted events.

⟨*HEP common: public*⟩+≡
```
   public :: heprup_get_run_parameters
```

⟨*HEP common: procedures*⟩+≡
```
   subroutine heprup_get_run_parameters &
        (beam_pdg, beam_energy, n_processes, unweighted, negative_weights)
     integer, dimension(2), intent(out), optional :: beam_pdg
     real(default), dimension(2), intent(out), optional :: beam_energy
     integer, intent(out), optional :: n_processes
     logical, intent(out), optional :: unweighted
     logical, intent(out), optional :: negative_weights
     if (present (beam_pdg))  beam_pdg = IDBMUP
     if (present (beam_energy))  beam_energy = EBMUP
     if (present (n_processes))  n_processes = NPRUP
     if (present (unweighted)) then
        select case (abs (IDWTUP))
        case (3)
           unweighted = .true.
        case (4)
           unweighted = .false.
        case (1,2)  ! not supported by WHIZARD
           unweighted = .false.
        case default
           call msg_fatal ("HEPRUP: unsupported IDWTUP value")
        end select
     end if
     if (present (negative_weights)) then
        negative_weights = IDWTUP < 0
     end if
   end subroutine heprup_get_run_parameters
```

Specify PDF set info. Since we support only LHAPDF, the group entry is zero.

⟨*HEP common: public*⟩+≡
```
   public :: heprup_set_lhapdf_id
```

⟨*HEP common: procedures*⟩+≡
```
   subroutine heprup_set_lhapdf_id (i_beam, pdf_id)
     integer, intent(in) :: i_beam, pdf_id
     PDFGUP(i_beam) = 0
     PDFSUP(i_beam) = pdf_id
   end subroutine heprup_set_lhapdf_id
```

Fill the characteristics for a particular process. Only the process ID is mandatory. Note that WHIZARD computes cross sections in fb, so we have to rescale to pb. The maximum weight is meaningless for unweighted events.

⟨*HEP common: public*⟩+≡
```
    public :: heprup_set_process_parameters
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine heprup_set_process_parameters &
         (i, process_id, cross_section, error, max_weight)
      integer, intent(in) :: i, process_id
      real(default), intent(in), optional :: cross_section, error, max_weight
      real(default), parameter :: pb_per_fb = 1.e-3_default
      LPRUP(i) = process_id
      if (present (cross_section)) then
         XSECUP(i) = cross_section * pb_per_fb
      else
         XSECUP(i) = 0
      end if
      if (present (error)) then
         XERRUP(i) = error * pb_per_fb
      else
         XERRUP(i) = 0
      end if
      select case (IDWTUP)
      case (3);  XMAXUP(i) = 1
      case (4)
         if (present (max_weight)) then
            XMAXUP(i) = max_weight * pb_per_fb
         else
            XMAXUP(i) = 0
         end if
      end select
    end subroutine heprup_set_process_parameters
```

Extract the process parameters, as far as needed.

⟨*HEP common: public*⟩+≡
```
    public :: heprup_get_process_parameters
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine heprup_get_process_parameters  &
         (i, process_id, cross_section, error, max_weight)
      integer, intent(in) :: i
      integer, intent(out), optional :: process_id
      real(default), intent(out), optional :: cross_section, error, max_weight
      real(default), parameter :: pb_per_fb = 1.e-3_default
      if (present (process_id))  process_id = LPRUP(i)
      if (present (cross_section)) then
         cross_section = XSECUP(i) / pb_per_fb
      end if
      if (present (error)) then
         error = XERRUP(i) / pb_per_fb
      end if
      if (present (max_weight)) then
         select case (IDWTUP)
```

```
       case (3)
          max_weight = 1
       case (4)
          max_weight = XMAXUP(i) / pb_per_fb
       case (1,2)   ! not supported by WHIZARD
          max_weight = 0
       case default
          call msg_fatal ("HEPRUP: unsupported IDWTUP value")
       end select
    end if
end subroutine heprup_get_process_parameters
```

19.5.4   Run parameter output (verbose)

This is a verbose output of the HEPRUP block.

⟨*HEP common: public*⟩+≡
```
    public :: heprup_write_verbose
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine heprup_write_verbose (unit)
      integer, intent(in), optional :: unit
      integer :: u, i
      u = output_unit (unit);  if (u < 0)  return
      write (u, "(A)")  "HEPRUP Common Block"
      write (u, "(3x,A6,' = ',I9,3x,1x,I9,3x,8x,A)")  "IDBMUP", IDBMUP, &
           "PDG code of beams"
      write (u, "(3x,A6,' = ',G12.5,1x,G12.5,8x,A)")  "EBMUP ", EBMUP, &
           "Energy of beams in GeV"
      write (u, "(3x,A6,' = ',I9,3x,1x,I9,3x,8x,A)")  "PDFGUP", PDFGUP, &
           "PDF author group [-1 = undefined]"
      write (u, "(3x,A6,' = ',I9,3x,1x,I9,3x,8x,A)")  "PDFSUP", PDFSUP, &
           "PDF set ID      [-1 = undefined]"
      write (u, "(3x,A6,' = ',I9,3x,1x,9x,3x,8x,A)")  "IDWTUP", IDWTUP, &
           "LHA code for event weight mode"
      write (u, "(3x,A6,' = ',I9,3x,1x,9x,3x,8x,A)")  "NPRUP ", NPRUP, &
           "Number of user subprocesses"
      do i = 1, NPRUP
         write (u, "(1x,A,I0)")  "Subprocess #", i
         write (u, "(3x,A6,' = ',ES12.5,1x,12x,8x,A)")  "XSECUP", XSECUP(i), &
              "Cross section in pb"
         write (u, "(3x,A6,' = ',ES12.5,1x,12x,8x,A)")  "XERRUP", XERRUP(i), &
              "Cross section error in pb"
         write (u, "(3x,A6,' = ',ES12.5,1x,12x,8x,A)")  "XMAXUP", XMAXUP(i), &
              "Maximum event weight (cf. IDWTUP)"
         write (u, "(3x,A6,' = ',I9,3x,1x,12x,8x,A)")  "LPRUP ", LPRUP(i), &
              "Subprocess ID"
      end do
    end subroutine heprup_write_verbose
```

19.5.5 Run parameter output (other formats)

This routine writes the initialization block according to the LHEF standard. It uses the current contents of the HEPRUP block.

⟨*HEP common: public*⟩+≡
```
    public :: heprup_write_lhef
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine heprup_write_lhef (unit)
      integer, intent(in), optional :: unit
      integer :: u, i
      u = output_unit (unit);  if (u < 0)  return
      write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
           IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
      do i = 1, NPRUP
         write (u, "(3(1x,ES17.10),1x,I0)") &
              XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
      end do
    end subroutine heprup_write_lhef
```

This routine is a complete dummy at the moment. It uses the current contents of the HEPRUP block. At the end, it should depend on certain input flags for the different ASCII event formats.

⟨*HEP common: public*⟩+≡
```
    public :: heprup_write_ascii
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine heprup_write_ascii (unit)
      integer, intent(in), optional :: unit
      integer :: u, i
      u = output_unit (unit);  if (u < 0)  return
      write (u, "(2(1x,I0),2(1x,ES17.10),6(1x,I0))") &
           IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
      do i = 1, NPRUP
         write (u, "(3(1x,ES17.10),1x,I0)") &
              XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
      end do
    end subroutine heprup_write_ascii
```

Run parameter input (LHEF)

In a LHEF file, the parameters are written in correct order on separate lines, but we should not count on the precise format. List-directed input should just work.

⟨*HEP common: public*⟩+≡
```
    public :: heprup_read_lhef
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine heprup_read_lhef (u)
      integer, intent(in) :: u
      integer :: i
      read (u, *) &
           IDBMUP, EBMUP, PDFGUP, PDFSUP, IDWTUP, NPRUP
```

2565

```
      do i = 1, NPRUP
         read (u, *) &
              XSECUP(i), XERRUP(i), XMAXUP(i), LPRUP(i)
      end do
   end subroutine heprup_read_lhef
```

19.5.6   The HEPEUP common block

⟨*HEP common: common blocks*⟩+≡
```
   common /HEPEUP/ &
        NUP, IDPRUP, XWGTUP, SCALUP, AQEDUP, AQCDUP, &
        IDUP, ISTUP, MOTHUP, ICOLUP, PUP, VTIMUP, SPINUP
   save /HEPEUP/
```

Initialization

Fill the event characteristics of the common block. The initialization sets only
the number of particles and initializes the rest with default values. The other
routine sets the optional parameters.

⟨*HEP common: public*⟩+≡
```
   public :: hepeup_init
   public :: hepeup_set_event_parameters
```

⟨*HEP common: procedures*⟩+≡
```
   subroutine hepeup_init (n_tot)
     integer, intent(in) :: n_tot
     NUP = n_tot
     IDPRUP = 0
     XWGTUP = 1
     SCALUP = -1
     AQEDUP = -1
     AQCDUP = -1
   end subroutine hepeup_init

   subroutine hepeup_set_event_parameters &
       (proc_id, weight, scale, alpha_qed, alpha_qcd)
     integer, intent(in), optional :: proc_id
     real(default), intent(in), optional :: weight, scale, alpha_qed, alpha_qcd
     if (present (proc_id))   IDPRUP = proc_id
     if (present (weight))    XWGTUP = weight
     if (present (scale))     SCALUP = scale
     if (present (alpha_qed)) AQEDUP = alpha_qed
     if (present (alpha_qcd)) AQCDUP = alpha_qcd
   end subroutine hepeup_set_event_parameters
```

Extract event information. The caller determines the parameters.

⟨*HEP common: public*⟩+≡
```
   public :: hepeup_get_event_parameters
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine hepeup_get_event_parameters &
         (proc_id, weight, scale, alpha_qed, alpha_qcd)
      integer, intent(out), optional :: proc_id
      real(default), intent(out), optional :: weight, scale, alpha_qed, alpha_qcd
      if (present (proc_id))   proc_id   = IDPRUP
      if (present (weight))    weight    = XWGTUP
      if (present (scale))     scale     = SCALUP
      if (present (alpha_qed)) alpha_qed = AQEDUP
      if (present (alpha_qcd)) alpha_qcd = AQCDUP
    end subroutine hepeup_get_event_parameters
```

Particle data

Below we need the particle status codes which are actually defined in the `subevents` module.

   Set the entry for a specific particle. All parameters are set with the exception of lifetime and spin, where default values are stored.

⟨*HEP common: public*⟩+≡
```
    public :: hepeup_set_particle
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine hepeup_set_particle (i, pdg, status, parent, col, p, m2)
      integer, intent(in) :: i
      integer, intent(in) :: pdg, status
      integer, dimension(:), intent(in) :: parent
      type(vector4_t), intent(in) :: p
      integer, dimension(2), intent(in) :: col
      real(default), intent(in) :: m2
      if (i > MAXNUP) then
         call msg_error (arr=[ &
              var_str ("Too many particles in HEPEUP common block. " // &
                          "If this happened "), &
              var_str ("during event output, your events will be " // &
                          "invalid; please consider "), &
              var_str ("switching to a modern event format like HEPMC. " // &
                          "If you are not "), &
              var_str ("using an old, HEPEUP based format and " // &
                          "nevertheless get this error,"), &
              var_str ("please notify the WHIZARD developers,") ])
         return
      end if
      IDUP(i) = pdg
      select case (status)
      case (PRT_BEAM);         ISTUP(i) = -9
      case (PRT_INCOMING);     ISTUP(i) = -1
      case (PRT_BEAM_REMNANT); ISTUP(i) =  3
      case (PRT_OUTGOING);     ISTUP(i) =  1
      case (PRT_RESONANT);     ISTUP(i) =  2
      case (PRT_VIRTUAL);      ISTUP(i) =  3
      case default;            ISTUP(i) =  0
      end select
      select case (size (parent))
```

```
      case (0);      MOTHUP(:,i) = 0
      case (1);      MOTHUP(1,i) = parent(1); MOTHUP(2,i) = 0
      case default;  MOTHUP(:,i) = [ parent(1), parent(size (parent)) ]
      end select
      if (col(1) > 0) then
         ICOLUP(1,i) = 500 + col(1)
      else
         ICOLUP(1,i) = 0
      end if
      if (col(2) > 0) then
         ICOLUP(2,i) = 500 + col(2)
      else
         ICOLUP(2,i) = 0
      end if
      PUP(1:3,i) = vector3_get_components (space_part (p))
      PUP(4,i) = energy (p)
      PUP(5,i) = sign (sqrt (abs (m2)), m2)
      VTIMUP(i) = 0
      SPINUP(i) = 9
   end subroutine hepeup_set_particle
```

Set the lifetime, actually $c\tau$ measured im mm, where τ is the invariant lifetime.

⟨*HEP common: public*⟩+≡
```
   public :: hepeup_set_particle_lifetime
```

⟨*HEP common: procedures*⟩+≡
```
   subroutine hepeup_set_particle_lifetime (i, lifetime)
     integer, intent(in) :: i
     real(default), intent(in) :: lifetime
     VTIMUP(i) = lifetime
   end subroutine hepeup_set_particle_lifetime
```

Set the particle spin entry. We need the cosine of the angle of the spin axis with respect to the three-momentum of the parent particle.

If the particle has a full polarization density matrix given, we need the particle momentum and polarization as well as the mother-particle momentum. The polarization is transformed into a spin vector (which is sensible only for spin-1/2 or massless particles), which then is transformed into the lab frame (by a rotation of the 3-axis to the particle momentum axis). Finally, we compute the scalar product of this vector with the mother-particle three-momentum.

This puts severe restrictions on the applicability of this definition, and Lorentz invariance is lost. Unfortunately, the Les Houches Accord requires this computation.

⟨*HEP common: public*⟩+≡
```
   public :: hepeup_set_particle_spin
```

⟨*HEP common: interfaces*⟩≡
```
   interface hepeup_set_particle_spin
      module procedure hepeup_set_particle_spin_pol
   end interface
```

⟨*HEP common: procedures*⟩+≡
```
   subroutine hepeup_set_particle_spin_pol (i, p, pol, p_mother)
```

```
      integer, intent(in) :: i
      type(vector4_t), intent(in) :: p
      type(polarization_t), intent(in) :: pol
      type(vector4_t), intent(in) :: p_mother
      type(vector3_t) :: s3, p3
      type(vector4_t) :: s4
      s3 = vector3_moving (polarization_get_axis (pol))
      p3 = space_part (p)
      s4 = rotation_to_2nd (3, p3) * vector4_moving (0._default, s3)
      SPINUP(i) = enclosed_angle_ct (s4, p_mother)
   end subroutine hepeup_set_particle_spin_pol
```

Extract particle data. The caller decides which ones to retrieve.

Status codes: beam remnants share the status code with virtual particles. However, for the purpose of WHIZARD we should identify them. We use the PDG code for this.

⟨*HEP common: public*⟩+≡
```
    public :: hepeup_get_particle
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine hepeup_get_particle (i, pdg, status, parent, col, p, m2)
      integer, intent(in) :: i
      integer, intent(out), optional :: pdg, status
      integer, dimension(:), intent(out), optional :: parent
      type(vector4_t), intent(out), optional :: p
      integer, dimension(2), intent(out), optional :: col
      real(default), dimension(5,MAXNUP) :: pup_def
      real(default), intent(out), optional :: m2
      if (present (pdg))  pdg = IDUP(i)
      if (present (status)) then
         select case (ISTUP(i))
         case (-9);  status = PRT_BEAM
         case (-1);  status = PRT_INCOMING
         case (1);   status = PRT_OUTGOING
         case (2);   status = PRT_RESONANT
         case (3);

      col = ICOLUP(:,i)
   end if
   if (present (p)) then
      pup_def = PUP
      p = vector4_moving (pup_def(4,i), vector3_moving (pup_def(1:3,i)))
   end if
   if (present (m2)) then
      m2 = sign (PUP(5,i) ** 2, PUP(5,i))
   end if
end subroutine hepeup_get_particle
```

19.5.7 The HEPEVT common block

For the LEP Monte Carlos, a standard common block has been proposed in
AKV89. We strongly recommend its use. (The description is an abbreviated
transcription of AKV89, Vol. 3, pp. 327-330).

NMXHEP is the maximum number of entries:

⟨*HEP common: variables*⟩+≡
```
   integer, parameter :: NMXHEP = 4000
```

NEVHEP is normally the event number, but may take special values as follows:

0 the program does not keep track of event numbers. -1 a special initializa-
tion record. -2 a special final record.

⟨*HEP common: variables*⟩+≡
```
   integer :: NEVHEP
```

NHEP holds the number of entries for this event.

⟨*HEP common: variables*⟩+≡
```
   integer :: NHEP
```

The entry ISTHEP(N) gives the status code for the Nth entry, with the following
semantics: 0 a null entry. 1 an existing entry, which has not decayed or frag-
mented. 2 a decayed or fragmented entry, which is retained for event history
information. 3 documentation line. 4- 10 reserved for future standards. 11-200
at the disposal of each model builder. 201- at the disposal of users.

⟨*HEP common: variables*⟩+≡
```
   integer, dimension(NMXHEP) :: ISTHEP
```

The Particle Data Group has proposed standard particle codes, which are to be
stored in IDHEP(N).

⟨*HEP common: variables*⟩+≡
```
   integer, dimension(NMXHEP) :: IDHEP
```

JMOHEP(1,N) points to the mother of the Nth entry, if any. It is set to zero for
initial entries. JMOHEP(2,N) points to the second mother, if any.

⟨*HEP common: variables*⟩+≡
```
   integer, dimension(2, NMXHEP) :: JMOHEP
```

`JDAHEP(1,N)` and `JDAHEP(2,N)` point to the first and last daughter of the `N`th entry, if any. These are zero for entries which have not yet decayed. The other daughters are stored in between these two.

⟨*HEP common: variables*⟩+≡
```
integer, dimension(2, NMXHEP) :: JDAHEP
```

In `PHEP` we store the momentum of the particle, more specifically this means that `PHEP(1,N)`, `PHEP(2,N)`, and `PHEP(3,N)` contain the momentum in the x, y, and z direction (as defined by the machine people), measured in GeV/c. `PHEP(4,N)` contains the energy in GeV and `PHEP(5,N)` the mass in GeV/c^2. The latter may be negative for spacelike partons.

⟨*HEP common: variables*⟩+≡
```
double precision, dimension(5, NMXHEP) :: PHEP
```

Finally `VHEP` is the place to store the position of the production vertex. `VHEP(1,N)`, `VHEP(2,N)`, and `VHEP(3,N)` contain the x, y, and z coordinate (as defined by the machine people), measured in mm. `VHEP(4,N)` contains the production time in mm/c.

⟨*HEP common: variables*⟩+≡
```
double precision, dimension(4, NMXHEP) :: VHEP
```

As an amendment to the proposed standard common block HEPEVT, we also have a polarisation common block HEPSPN, as described in AKV89. `SHEP(1,N)`, `SHEP(2,N)`, and `SHEP(3,N)` give the x, y, and z component of the spinvector s of a fermion in the fermions restframe.

Furthermore, we add the polarization of the corresponding outgoing particles:

⟨*HEP common: variables*⟩+≡
```
integer, dimension(NMXHEP) :: hepevt_pol
```

By convention, `SHEP(4,N)` is always 1. All this is taken from StdHep 4.06 manual and written using Fortran90 conventions.

⟨*HEP common: common blocks*⟩+≡
```
common /HEPEVT/ &
     NEVHEP, NHEP, ISTHEP, IDHEP, &
     JMOHEP, JDAHEP, PHEP, VHEP
save /HEPEVT/
```

Here we store HEPEVT parameters of the WHIZARD 1 realization which are not part of the HEPEVT common block.

⟨*HEP common: variables*⟩+≡
```
integer :: hepevt_n_out, hepevt_n_remnants
```

⟨*HEP common: variables*⟩+≡
```
double precision :: hepevt_weight, hepevt_function_value
double precision :: hepevt_function_ratio
```

Filling HEPEVT: If the event count is not provided, set `NEVHEP` to zero. If the event count is `-1` or `-2`, the record corresponds to initialization and finalization, and the event is irrelevant.

Note that the event count may be larger than 2^{31} (2 GEvents). In that case, cut off the upper bits since `NEVHEP` is probably limited to default integer.

⟨*HEP common: public*⟩+≡
```
    public :: hepevt_init
    public :: hepevt_set_event_parameters
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine hepevt_init (n_tot, n_out)
      integer, intent(in) :: n_tot, n_out
      NHEP              = n_tot
      NEVHEP            = 0

end do

end subroutine hepeup_write_lha
```

This routine writes event output according to the HEPEVT standard. It uses
the current contents of the HEPEVT block and some additional parameters ac-
cording to the standard in WHIZARD 1. For the long ASCII format, the value
of the sample function (i.e. the product of squared matrix element, structure
functions and phase space factor is printed out). The option of reweighting ma-
trix elements with respect to some reference cross section is not implemented in
WHIZARD 2 for this event format, therefore the second entry in the long ASCII
format (the function ratio) is always one. The ATHENA format is an imple-
mentation of the HEPEVT format that is readable by the ATLAS ATHENA
software framework. It is very similar to the WHIZARD 1 HEPEVT format,
except that it contains an event counter, a particle counter inside the event, and
has the HEPEVT ISTHEP status before the PDG code. The MOKKA format
is a special ASCII format that contains the information to be parsed to the
MOKKA LC fast simulation software.

19.5.11   Data Transfer: particle sets

The `WHIZARD` format for handling particle data in events is `particle_set_t`.
We have to interface this to the common blocks.

We first create a new particle set that contains only the particles that are
supported by the LHEF format. These are: beam, incoming, resonant, outgoing.
We drop particles with unknown, virtual or beam-remnant status.

From this set we fill the common block. Event information such as process
ID and weight is not transferred here; this has to be done by the caller. The spin
information is set only if the particle has a unique mother, and if its polarization
is fully defined.

⟨*HEP common: public*⟩+≡
```
   public :: hepeup_from_particle_set
```

⟨*HEP common: procedures*⟩+≡
```
   subroutine hepeup_from_particle_set (particle_set, keep_beams)
     type(particle_set_t), intent(in), target :: particle_set
     logical, intent(in), optional :: keep_beams
     type(particle_t), pointer :: prt
     type(particle_set_t), target :: pset_hepevt
     integer :: i, n_parents
     integer, dimension(1) :: i_mother
     call particle_set_to_hepevt_form (particle_set, pset_hepevt, keep_beams)
     call hepeup_init (pset_hepevt%n_tot)
     do i = 1, pset_hepevt%n_tot
        prt => pset_hepevt%prt(i)
        call hepeup_set_particle (i, &
             particle_get_pdg (prt), &
             particle_get_status (prt), &
             particle_get_parents (prt), &
             particle_get_color (prt), &
             particle_get_momentum (prt), &
             particle_get_p2 (prt))
        n_parents = particle_get_n_parents (prt)
        if (n_parents == 1) then
           i_mother = particle_get_parents (prt)
           select case (particle_get_polarization_status (prt))
           case (PRT_GENERIC_POLARIZATION)
              call hepeup_set_particle_spin (i, &
                   particle_get_momentum (prt), &
                   particle_get_polarization (prt), &
                   particle_get_momentum (pset_hepevt%prt(i_mother(1))))
           end select
        end if
     end do
     call particle_set_final (pset_hepevt)
```

```
      end subroutine hepeup_from_particle_set
```

Input. The particle set should be allocated properly, but we replace the particle contents.

If there are no beam particles in the event, we try to reconstruct beam particles and beam remnants. We assume for simplicity that the beam particles, if any, are the first two particles. If they are absent, the first two particles should be the incoming partons.

```
                call particle_set_children (prt(k), [k+2,k+4])
            end do
            do k = 3, 4
                call particle_reset_status (prt(k), PRT_BEAM_REMNANT)
                call particle_set_parents (prt(k), [k-2])
            end do
            do k = 5, 6
                call particle_set_parents (prt(k), [k-4])
            end do
        else
            call handle_beams (prt)
        end if
        call particle_set_replace (particle_set, prt)
    end subroutine hepeup_to_particle_set
```

Beams and beam remnants require a special handling. `WHIZARD`'s interactions are set up such that in the list of children of beam particles, the remnant comes before the interacting parton. To enforce this, we may have to reorder things.

The beam particles will always be the first two particles.

⟨*HEP common: procedures*⟩+≡
```
    subroutine handle_beams (prt)
        type(particle_t), dimension(:), intent(inout) :: prt
        integer :: i
        integer, dimension(2) :: child
        do i = 1, 2
            select case (particle_get_status (prt(i)))
            case (PRT_BEAM)
                child = particle_get_children (prt(i))
                if (particle_get_status (prt(child(2))) == PRT_BEAM_REMNANT) then
                    call particle_set_children (prt(i), child([2,1]))
                end if
            end select
        end do
    end subroutine handle_beams
```

The HEPEVT common block is quite similar, but does contain less information, e.g. no color flows (it was LEP time). The spin information is set only if the particle has a unique mother, and if its polarization is fully defined.

⟨*HEP common: public*⟩+≡
```
    public :: hepevt_from_particle_set
```

⟨*HEP common: procedures*⟩+≡
```
    subroutine hepevt_from_particle_set (particle_set, keep_beams)
        type(particle_set_t), intent(in), target :: particle_set
        type(particle_t), pointer :: prt

      end do
      call particle_set_final (pset_hepevt)
    end subroutine hepevt_from_particle_set
```

19.6   HEP Common and Events

This is a separate module that manages data exchange between the common
blocks and `event_t` objects. We separate this from the previous module in
order to avoid a circular module dependency.

⟨`hep_events.f90`⟩≡
  ⟨*File header*⟩

```
  module hep_events

    use kinds !NODEP!
```
⟨*Use file utils*⟩
```
     use diagnostics !NODEP!

    use models
    use particles
    use processes
    use hep_common
    use events
```

⟨*Standard module head*⟩

⟨*HEP events: public*⟩

```
  contains
```

⟨*HEP events: procedures*⟩

```
  end module hep_events
```

19.6.1   Data Transfer: events

Fill the HEPEUP block, given a `WHIZARD` event object.

⟨*HEP events: public*⟩≡
```
    public :: hepeup_from_event
```

⟨*HEP events: procedures*⟩≡
```
    subroutine hepeup_from_event (event, keep_beams, process_index)
      type(event_t), intent(in), target :: event
      logical, intent(in), optional :: keep_beams
```

```
        integer, intent(in), optional :: process_index
        type(particle_set_t), pointer :: particle_set
        real(default) :: scale, alpha_qcd
        if (event%has_particle_set ()) then
           particle_set => event%get_particle_set_ptr ()
           call hepeup_from_particle_set (particle_set, keep_beams)
           if (present (process_index)) &
                call hepeup_set_event_parameters (proc_id = process_index)
           scale = event%get_fac_scale ()
           if (scale /= 0) &
                call hepeup_set_event_parameters (scale = scale)
           alpha_qcd = event%get_alpha_s ()
           if (alpha_qcd /= 0) &
                call hepeup_set_event_parameters (alpha_qcd = alpha_qcd)
           if (event%weight_prc_is_known) then
              call hepeup_set_event_parameters (weight = event%weight_prc)
           else
              call msg_bug ("HEPEUP: process weight is unknown")
           end if
        else
           call msg_bug ("HEPEUP: event incomplete")
        end if
     end subroutine hepeup_from_event
```

Reverse.

Note: The current implementation sets the particle set of the hard process and is therefore not useful if the event on file is dressed. This should be reconsidered.

Note: setting of scale or alpha is not yet supported by the `event_t` object. Ticket #628.

⟨*HEP events: public*⟩+≡
```
     public :: hepeup_to_event
```

⟨*HEP events: procedures*⟩+≡
```
     subroutine hepeup_to_event (event, process_index, recover_beams)
       type(event_t), intent(inout), target :: event
       integer, intent(out), optional :: process_index
       logical, intent(in), optional :: recover_beams
       type(process_t), pointer :: process
       type(model_t), pointer :: model
       real(default) :: weight, scale, alpha_qcd
       type(particle_set_t) :: particle_set
       process => event%get_process_ptr ()
       model => process%get_model_ptr ()
       call hepeup_to_particle_set (particle_set, recover_beams, model)
       call event%set_particle_set_hard_proc (particle_set)
       call particle_set_final (particle_set)
       if (present (process_index)) then
          call hepeup_get_event_parameters (proc_id = process_index)
       end if
       call hepeup_get_event_parameters (weight = weight, &
            scale = scale, alpha_qcd = alpha_qcd)
       call event%set (weight_ref = weight)
  !!! Not implemented yet:
```

```
!      if (scale > 0)  call event%set_scales (scale)
!      if (alpha_qcd > 0)  call event%set_alpha_qcd (alpha_qcd)
   end subroutine hepeup_to_event
```

Fill the HEPEVT (event) common block:

⟨*HEP events: public*⟩+≡
```
    public :: hepevt_from_event
```

⟨*HEP events: procedures*⟩+≡
```
    subroutine hepevt_from_event (event, i_evt, keep_beams)
      type(event_t), intent(in), target :: event
      integer, intent(in), optional :: i_evt
      logical, intent(in), optional :: keep_beams
      type(particle_set_t), pointer :: particle_set
      if (event%has_particle_set ()) then
         particle_set => event%get_particle_set_ptr ()
         call hepevt_from_particle_set (particle_set, keep_beams)
         if (event%weight_prc_is_known .and. event%sqme_prc_is_known) then
            call hepevt_set_event_parameters ( &
                 weight = event%weight_prc, &
                 function_value = event%sqme_prc)
         else
            call msg_bug ("HEPEVT: event weight and/or sqme unknown")
         end if
         if (present (i_evt)) &
              call hepevt_set_event_parameters (i_evt = i_evt)
      else
         call msg_bug ("HEPEVT: event incomplete")
      end if
    end subroutine hepevt_from_event
```

19.7   LHEF Input/Output

The LHEF event record is standardized. It is an ASCII format. We try our best at using it for both input and output.

Input an event. Upon input of `i_prc`, we can just read in the whole HEPEUP common block. These data are known to come first. The `i_prc` value can be deduced from the IDPRUP value by a table lookup.

Reading the common block bypasses the `cstream` which accesses the input unit. This is consistent with the LHEF specification. After the common-block data have been swallowed, we can resume reading from stream.

We don't catch actual I/O errors. However, we return a negative value in `iostat` if we reached the terminating `</LesHouchesEvents>` tag.

Since we have already read the event information from file, this input routine can transfer the common-block contents to the event record. Also, we read any further information in the event record.

Since LHEF doesn't give this information, we must assume that the MCI group, term, and channel can all be safely set to 1. This works if there is only one MCI group and term. The channel doesn't matter for the matrix element.

19.7.5   Version-Specific Code: 1.0

In version 1.0, the init tag contains just HEPRUP data. While a `cstream` is
connected to the input unit, we bypass it temporarily for the purpose of reading
the HEPRUP contents. This is consistent with the LHEF standard.

This routine does not read the closing tag of the init block.

⟨*EIO LHEF: eio lhef: TBP*⟩+≡
```

              error = data%error(i))
      end do
    end subroutine eio_lhef_read_init_10
```

19.7.6 Version-Specific Code: 2.0

This is the init information for the 2.0 format, after the HEPRUP data. We have the following tags:

- `generator` Generator name and version.

- `xsecinfo` Cross section and weights data. We have the total cross section and number of events (assuming that the event file is intact), but information on minimum and maximum weights is not available before the file is complete. We just write the mandatory tags. (Note that the default values of the other tags describe a uniform unit weight, but we can determine most values only after the sample is complete.)

- `cutsinfo` This optional tag is too specific to represent the possibilities of WHIZARD, so we skip it.

- `procinfo` This optional tag is useful for giving details of NLO calculations. Skipped.

- `mergetype` Optional, also not applicable.

⟨*EIO LHEF: eio lhef: TBP*⟩+≡
```
    procedure :: write_init_20 => eio_lhef_write_init_20
```

⟨*EIO LHEF: procedures*⟩+≡
```
    subroutine eio_lhef_write_init_20 (eio, data)
      class(eio_lhef_t), intent(in) :: eio
      type(event_sample_data_t), intent(in) :: data
      integer :: u
      u = eio%unit
      call eio%tag_generator%write (u)
      write (u, "(A)", advance="no")  "WHIZARD"
      call eiO%tag_generator%close (u);  write (u, *)
      call eio%tag_xsecinfo%write (u);  write (u, *)
    end subroutine eio_lhef_write_init_20
```

When reading the init block, we first call the 1.0 routine that fills HEPRUP. Then we consider the possible tags. Only the `generator` and `xsecinfo` tags are of interest. We skip everything else except for the closing tag.

⟨*EIO LHEF: eio lhef: TBP*⟩+≡

19.7.8 Auxiliary

Create a string from a number. We use fixed format for the reals and variable format for integers.

⟨*EIO LHEF: interfaces*⟩≡
```
interface str
   module procedure str_int, str_real
end interface
```

⟨*EIO LHEF: procedures*⟩+≡

```
function str_int (i) result (s)
  integer, intent(in) :: i
  type(string_t) :: s
  character(32) :: buffer
  write (buffer, "(I0)")  i
  s = var_str (trim (buffer))
end function str_int

function str_real (x) result (s)
  real(default), intent(in) :: x
  type(string_t) :: s
  character(32) :: buffer
  write (buffer, "(ES17.10)")  x
  s = var_str (trim (adjustl (buffer)))
end function str_real
```

Auxiliary: Read real, integer, string value.

⟨*EIO LHEF: procedures*⟩+≡

```
function read_rval (s) result (rval)
  type(string_t), intent(in) :: s
  real(default) :: rval
  character(80) :: buffer
  buffer = s
  read (buffer, *)  rval
end function read_rval

function read_ival (s) result (ival)
  type(string_t), intent(in) :: s
  integer :: ival
  character(80) :: buffer
  buffer = s
  read (buffer, *)  ival
end function read_ival
```

19.7.9 Unit tests

⟨*EIO LHEF: public*⟩+≡

```
public :: eio_lhef_test
```

⟨*EIO LHEF: tests*⟩≡

```
subroutine eio_lhef_test (u, results)
  integer, intent(in) :: u
  type(test_results_t), intent(inout) :: results
  ⟨EIO LHEF: execute tests⟩
end subroutine eio_lhef_test
```

Version 1.0 Output

We test the implementation of all I/O methods. We start with output according to version 1.0.

⟨*EIO LHEF: execute tests*⟩≡
```
    call test (eio_lhef_1, "eio_lhef_1", &
         "write version 1.0", &
         u, results)
```
⟨*EIO LHEF: tests*⟩+≡

19.8   HepMC events

This section provides the interface to the HepMC C++ library for handling Monte-Carlo events.

Each C++ class of HepMC that we use is mirrored by a Fortran type, which contains as its only component the C pointer to the C++ object.

Each C++ method of HepMC that we use has a C wrapper function. This function takes a pointer to the host object as its first argument. Further arguments are either C pointers, or in the case of simple types (integer, real),

interoperable C/Fortran objects.

The C wrapper functions have explicit interfaces in the Fortran module. They are called by Fortran wrapper procedures. These are treated as methods of the corresponding Fortran type.

  ⟨*HepMC interface: procedures*⟩

  ⟨*HepMC interface: tests*⟩

  end module hepmc_interface

19.8.1   Interface check

This function can be called in order to verify that we are using the actual HepMC library, and not the dummy version.

⟨*HepMC interface: interfaces*⟩≡
    interface
       logical(c_bool) function hepmc_available () bind(C)
         import
       end function hepmc_available
    end interface

⟨*HepMC interface: public*⟩≡
    public :: hepmc_is_available

⟨*HepMC interface: procedures*⟩≡
```
function hepmc_is_available () result (flag)
  logical :: flag
  flag = hepmc_available ()
end function hepmc_is_available
```

19.8.2 FourVector

The C version of four-vectors is often transferred by value, and the associated procedures are all inlined. The wrapper needs to transfer by reference, so we create FourVector objects on the heap which have to be deleted explicitly. The input is a `vector4_t` or `vector3_t` object from the `lorentz` module.

⟨*HepMC interface: public*⟩+≡
```
public :: hepmc_four_vector_t
```

⟨*HepMC interface: types*⟩≡
```
type :: hepmc_four_vector_t
  private
  type(c_ptr) :: obj
end type hepmc_four_vector_t
```

In the C constructor, the zero-component (fourth argument) is optional; if missing, it is set to zero. The Fortran version has initializer form and takes either a three-vector or a four-vector. A further version extracts the four-vector from a HepMC particle object.

⟨*HepMC interface: interfaces*⟩+≡
```
interface
  type(c_ptr) function new_four_vector_xyz (x, y, z) bind(C)
    import
    real(c_double), value :: x, y, z
  end function new_four_vector_xyz
end interface
interface
  type(c_ptr) function new_four_vector_xyzt (x, y, z, t) bind(C)
    import
    real(c_double), value :: x, y, z, t
  end function new_four_vector_xyzt

      p3(3) = four_vector_pz (pp%obj)
      p = vector4_moving (E, vector3_moving (p3))
    end subroutine hepmc_four_vector_to_vector4
```

19.8.3 Polarization

Polarization objects are temporarily used for assigning particle polarization. We
add a flag `polarized`. If this is false, the polarization is not set and should not
be transferred to `hepmc_particle` objects.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_polarization_t
```

⟨*HepMC interface: types*⟩+≡
```
    type :: hepmc_polarization_t
      private
      logical :: polarized = .false.
      type(c_ptr) :: obj
    end type hepmc_polarization_t
```

Constructor. The C wrapper takes polar and azimuthal angle as arguments. The Fortran version allows for either a complete polarization density matrix, or for a definite (diagonal) helicity.

HepMC does not allow to specify the degree of polarization, therefore we have to map it to either 0 or 1. We choose 0 for polarization less than 0.5 *and 1 for polarization greater than* 0.5. *Even this simplification works only for spin-1/2 and for massless particles; massive vector bosons cannot be treated this way. In particular, zero helicity is always translated as unpolarized.*

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       type(c_ptr) function new_polarization (theta, phi) bind(C)
         import
         real(c_double), value :: theta, phi
       end function new_polarization
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_polarization_init
```

⟨*HepMC interface: interfaces*⟩+≡
```
    interface hepmc_polarization_init
       module procedure hepmc_polarization_init_pol
       module procedure hepmc_polarization_init_hel
       module procedure hepmc_polarization_init_int
    end interface
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_polarization_init_pol (hpol, pol)
      type(hepmc_polarization_t), intent(out) :: hpol
      type(polarization_t), intent(in) :: pol
      real(default) :: r, theta, phi
      if (polarization_is_polarized (pol)) then
         call polarization_to_angles (pol, r, theta, phi)
         if (r >= 0.5) then
            hpol%polarized = .true.
            hpol%obj = new_polarization &
                 (real (theta, c_double), real (phi, c_double))
         end if
      end if
    end subroutine hepmc_polarization_init_pol

```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_polarization_final (hpol)
      type(hepmc_polarization_t), intent(inout) :: hpol
      if (hpol%polarized)  call polarization_delete (hpol%obj)
    end subroutine hepmc_polarization_final
```

Recover polarization from HepMC polarization object (with the abovementioned deficiencies).

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       function polarization_theta (pol_obj) result (theta) bind(C)
         import
         real(c_double) :: theta
         type(c_ptr), value :: pol_obj
       end function polarization_theta
    end interface
    interface
       function polarization_phi (pol_obj) result (phi) bind(C)
         import
         real(c_double) :: phi
         type(c_ptr), value :: pol_obj
       end function polarization_phi
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_polarization_to_pol
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_polarization_to_pol (hpol, flv, pol)
      type(hepmc_polarization_t), intent(in) :: hpol
      type(flavor_t), intent(in) :: flv
      type(polarization_t), intent(out) :: pol
      real(default) :: theta, phi
      theta = polarization_theta (hpol%obj)
      phi = polarization_phi (hpol%obj)
      call polarization_init_angles (pol, flv, 1._default, theta, phi)
    end subroutine hepmc_polarization_to_pol
```

Recover helicity. Here, ϕ is ignored and only the sign of $\cos\theta$ is relevant, mapped to positive/negative helicity.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_polarization_to_hel
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_polarization_to_hel (hpol, flv, hel)
      type(hepmc_polarization_t), intent(in) :: hpol
      type(flavor_t), intent(in) :: flv
      type(helicity_t), intent(out) :: hel
      real(default) :: theta
      integer :: hmax
      theta = polarization_theta (hpol%obj)
      hmax = flavor_get_spin_type (flv) / 2
      call helicity_init (hel, sign (hmax, nint (cos (theta))))
    end subroutine hepmc_polarization_to_hel
```

19.8.4 GenParticle

Particle objects have the obvious meaning.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_particle_t
```

⟨*HepMC interface: types*⟩+≡
```
    type :: hepmc_particle_t
       private
       type(c_ptr) :: obj
    end type hepmc_particle_t
```

Constructor. The C version takes a FourVector object, which in the Fortran wrapper is created on the fly from a `vector4` Lorentz vector.

No destructor is needed as long as all particles are entered into vertex containers.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      type(c_ptr) function new_gen_particle (prt_obj, pdg_id, status) bind(C)
        import
        type(c_ptr), value :: prt_obj
        integer(c_int), value :: pdg_id, status
      end function new_gen_particle
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_particle_init
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_particle_init (prt, p, pdg, status)
      type(hepmc_particle_t), intent(out) :: prt
      type(vector4_t), intent(in) :: p
      integer, intent(in) :: pdg, status
      type(hepmc_four_vector_t) :: pp
      call hepmc_four_vector_init (pp, p)
      prt%obj = new_gen_particle (pp%obj, int (pdg, c_int), int (status, c_int))
      call hepmc_four_vector_final (pp)
    end subroutine hepmc_particle_init
```

Set the particle color flow.
⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       subroutine gen_particle_set_flow (prt_obj, code_index, code) bind(C)
         import
         type(c_ptr), value :: prt_obj
         integer(c_int), value :: code_index, code
       end subroutine gen_particle_set_flow
    end interface
```

Set the particle color. Either from a `color_t` object or directly from a pair of integers.
⟨*HepMC interface: interfaces*⟩+≡
```
    interface hepmc_particle_set_color
       module procedure hepmc_particle_set_color_col
       module procedure hepmc_particle_set_color_int
    end interface hepmc_particle_set_color
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_particle_set_color
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_particle_set_color_col (prt, col)
      type(hepmc_particle_t), intent(inout) :: prt
      type(color_t), intent(in) :: col
      integer(c_int) :: c
      c = color_get_col (col)
      if (c /= 0)  call gen_particle_set_flow (prt%obj, 1_c_int, c)
      c = color_get_acl (col)
      if (c /= 0)  call gen_particle_set_flow (prt%obj, 2_c_int, c)
    end subroutine hepmc_particle_set_color_col

    subroutine hepmc_particle_set_color_int (prt, col)
      type(hepmc_particle_t), intent(inout) :: prt
      integer, dimension(2), intent(in) :: col
      integer(c_int) :: c
      c = col(1)
      if (c /= 0)  call gen_particle_set_flow (prt%obj, 1_c_int, c)
      c = col(2)
      if (c /= 0)  call gen_particle_set_flow (prt%obj, 2_c_int, c)
    end subroutine hepmc_particle_set_color_int
```

Set the particle polarization. For the restrictions on particle polarization in HepMC, see above `hepmc_polarization_init`.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       subroutine gen_particle_set_polarization (prt_obj, pol_obj) bind(C)
         import
         type(c_ptr), value :: prt_obj, pol_obj
       end subroutine gen_particle_set_polarization
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_particle_set_polarization
```

⟨*HepMC interface: interfaces*⟩+≡
```
    interface hepmc_particle_set_polarization
       module procedure hepmc_particle_set_polarization_pol
       module procedure hepmc_particle_set_polarization_hel
       module procedure hepmc_particle_set_polarization_int
    end interface
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_particle_set_polarization_pol (prt, pol)
      type(hepmc_particle_t), intent(inout) :: prt
      type(polarization_t), intent(in) :: pol
      type(hepmc_polarization_t) :: hpol
      call hepmc_polarization_init (hpol, pol)
      if (hpol%polarized)  call gen_particle_set_polarization (prt%obj, hpol%obj)
      call hepmc_polarization_final (hpol)
    end subroutine hepmc_particle_set_polarization_pol

    subroutine hepmc_particle_set_polarization_hel (prt, hel)
      type(hepmc_particle_t), intent(inout) :: prt
      type(helicity_t), intent(in) :: hel
      type(hepmc_polarization_t) :: hpol
      call hepmc_polarization_init (hpol, hel)
      if (hpol%polarized)  call gen_particle_set_polarization (prt%obj, hpol%obj)
      call hepmc_polarization_final (hpol)
    end subroutine hepmc_particle_set_polarization_hel

    subroutine hepmc_particle_set_polarization_int (prt, hel)
      type(hepmc_particle_t), intent(inout) :: prt
      integer, intent(in) :: hel
      type(hepmc_polarization_t) :: hpol
      call hepmc_polarization_init (hpol, hel)
      if (hpol%polarized)  call gen_particle_set_polarization (prt%obj, hpol%obj)
      call hepmc_polarization_final (hpol)
    end subroutine hepmc_particle_set_polarization_int
```

Return the HepMC barcode (unique integer ID) of the particle.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       function gen_particle_barcode (prt_obj) result (barcode) bind(C)
         import
         integer(c_int) :: barcode
         type(c_ptr), value :: prt_obj
```

```
      end function gen_particle_barcode
   end interface
```

⟨*HepMC interface: public*⟩+≡
```
   public :: hepmc_particle_get_barcode
```

⟨*HepMC interface: procedures*⟩+≡
```
   function hepmc_particle_get_barcode (prt) result (barcode)
     integer :: barcode
     type(hepmc_particle_t), intent(in) :: prt
     barcode = gen_particle_barcode (prt%obj)
   end function hepmc_particle_get_barcode
```

Return the four-vector component of the particle object as a `vector4_t` Lorentz vector.

⟨*HepMC interface: interfaces*⟩+≡
```
   interface
      type(c_ptr) function gen_particle_momentum (prt_obj) bind(C)
        import
        type(c_ptr), value :: prt_obj
      end function gen_particle_momentum
   end interface
```

⟨*HepMC interface: public*⟩+≡
```
   public :: hepmc_particle_get_momentum
```

⟨*HepMC interface: procedures*⟩+≡
```
   function hepmc_particle_get_momentum (prt) result (p)
     type(vector4_t) :: p
     type(hepmc_particle_t), intent(in) :: prt
     type(hepmc_four_vector_t) :: pp
     call hepmc_four_vector_init (pp, prt)
     call hepmc_four_vector_to_vector4 (pp, p)
     call hepmc_four_vector_final (pp)
   end function hepmc_particle_get_momentum
```

Return the invariant mass squared of the particle object. HepMC stores the signed invariant mass (no squaring).

⟨*HepMC interface: interfaces*⟩+≡
```
   interface
      function gen_particle_generated_mass (prt_obj) result (mass) bind(C)
        import
        real(c_double) :: mass
        type(c_ptr), value :: prt_obj
      end function gen_particle_generated_mass
   end interface
```

⟨*HepMC interface: public*⟩+≡
```
   public :: hepmc_particle_get_mass_squared
```

⟨*HepMC interface: procedures*⟩+≡
```
   function hepmc_particle_get_mass_squared (prt) result (m2)
     real(default) :: m2
     type(hepmc_particle_t), intent(in) :: prt
     real(default) :: m
     m = gen_particle_generated_mass (prt%obj)
```

```
      m2 = sign (m**2, m)
    end function hepmc_particle_get_mass_squared
```

Return the PDG ID:

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       function gen_particle_pdg_id (prt_obj) result (pdg_id) bind(C)
         import
         integer(c_int) :: pdg_id
         type(c_ptr), value :: prt_obj
       end function gen_particle_pdg_id
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_particle_get_pdg
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_particle_get_pdg (prt) result (pdg)
      integer :: pdg
      type(hepmc_particle_t), intent(in) :: prt
      pdg = gen_particle_pdg_id (prt%obj)
    end function hepmc_particle_get_pdg
```

Return the status code:

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       function gen_particle_status (prt_obj) result (status) bind(C)
         import
         integer(c_int) :: status
         type(c_ptr), value :: prt_obj
       end function gen_particle_status
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_particle_get_status
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_particle_get_status (prt) result (status)
      integer :: status
      type(hepmc_particle_t), intent(in) :: prt
      status = gen_particle_status (prt%obj)
    end function hepmc_particle_get_status
```

Return the production/decay vertex (as a pointer, no finalization necessary).

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       type(c_ptr) function gen_particle_production_vertex (prt_obj) bind(C)
         import
         type(c_ptr), value :: prt_obj
       end function gen_particle_production_vertex
    end interface
    interface
       type(c_ptr) function gen_particle_end_vertex (prt_obj) bind(C)
         import
```

```
        type(c_ptr), value :: prt_obj
      end function gen_particle_end_vertex
    end interface
```

⟨HepMC interface: public⟩+≡
```
    public :: hepmc_particle_get_production_vertex
    public :: hepmc_particle_get_decay_vertex
```

⟨HepMC interface: procedures⟩+≡
```
    function hepmc_particle_get_production_vertex (prt) result (v)
      type(hepmc_vertex_t) :: v
      type(hepmc_particle_t), intent(in) :: prt
      v%obj = gen_particle_production_vertex (prt%obj)
    end function hepmc_particle_get_production_vertex

    function hepmc_particle_get_decay_vertex (prt) result (v)
      type(hepmc_vertex_t) :: v
      type(hepmc_particle_t), intent(in) :: prt
      v%obj = gen_particle_end_vertex (prt%obj)
    end function hepmc_particle_get_decay_vertex
```

Return the number of parents/children.

⟨HepMC interface: public⟩+≡
```
    public :: hepmc_particle_get_n_parents
    public :: hepmc_particle_get_n_children
```

⟨HepMC interface: procedures⟩+≡
```
    function hepmc_particle_get_n_parents (prt) result (n_parents)
      integer :: n_parents
      type(hepmc_particle_t), intent(in) :: prt
      type(hepmc_vertex_t) :: v
      v = hepmc_particle_get_production_vertex (prt)
      if (hepmc_vertex_is_valid (v)) then
         n_parents = hepmc_vertex_get_n_in (v)
      else
         n_parents = 0
      end if
    end function hepmc_particle_get_n_parents

    function hepmc_particle_get_n_children (prt) result (n_children)
      integer :: n_children
      type(hepmc_particle_t), intent(in) :: prt
      type(hepmc_vertex_t) :: v
      v = hepmc_particle_get_decay_vertex (prt)
      if (hepmc_vertex_is_valid (v)) then
         n_children = hepmc_vertex_get_n_out (v)
      else
         n_children = 0
      end if
    end function hepmc_particle_get_n_children
```

Convenience function: Return the array of parent particles for a given HepMC particle. The contents are HepMC barcodes that still have to be mapped to the particle indices.

⟨HepMC interface: public⟩+≡

```
      public :: hepmc_particle_get_parent_barcodes
      public :: hepmc_particle_get_child_barcodes
```
⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_particle_get_parent_barcodes (prt) result (parent_barcode)
      type(hepmc_particle_t), intent(in) :: prt
      integer, dimension(:), allocatable :: parent_barcode
      type(hepmc_vertex_t) :: v
      type(hepmc_vertex_particle_in_iterator_t) :: it
      integer :: i
      v = hepmc_particle_get_production_vertex (prt)
      if (hepmc_vertex_is_valid (v)) then
         allocate (parent_barcode (hepmc_vertex_get_n_in (v)))
         if (size (parent_barcode) /= 0) then
            call hepmc_vertex_particle_in_iterator_init (it, v)
            do i = 1, size (parent_barcode)
               parent_barcode(i) = hepmc_particle_get_barcode &
                    (hepmc_vertex_particle_in_iterator_get (it))
               call hepmc_vertex_particle_in_iterator_advance (it)
            end do
            call hepmc_vertex_particle_in_iterator_final (it)
         end if
      else
         allocate (parent_barcode (0))
      end if
    end function hepmc_particle_get_parent_barcodes

    function hepmc_particle_get_child_barcodes (prt) result (child_barcode)
      type(hepmc_particle_t), intent(in) :: prt
      integer, dimension(:), allocatable :: child_barcode
      type(hepmc_vertex_t) :: v
      type(hepmc_vertex_particle_out_iterator_t) :: it
      integer :: i
      v = hepmc_particle_get_decay_vertex (prt)
      if (hepmc_vertex_is_valid (v)) then
         allocate (child_barcode (hepmc_vertex_get_n_out (v)))
         call hepmc_vertex_particle_out_iterator_init (it, v)
         if (size (child_barcode) /= 0) then
            do i = 1, size (child_barcode)
               child_barcode(i) = hepmc_particle_get_barcode &
                    (hepmc_vertex_particle_out_iterator_get (it))
               call hepmc_vertex_particle_out_iterator_advance (it)
            end do
            call hepmc_vertex_particle_out_iterator_final (it)
         end if
      else
         allocate (child_barcode (0))
      end if
    end function hepmc_particle_get_child_barcodes
```

Return the polarization (assuming that the particle is completely polarized).
Note that the generated polarization object needs finalization.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
```

```
      type(c_ptr) function gen_particle_polarization (prt_obj) bind(C)
        import
        type(c_ptr), value :: prt_obj
      end function gen_particle_polarization
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_particle_get_polarization
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_particle_get_polarization (prt) result (pol)
      type(hepmc_polarization_t) :: pol
      type(hepmc_particle_t), intent(in) :: prt
      pol%obj = gen_particle_polarization (prt%obj)
    end function hepmc_particle_get_polarization
```

Return the particle color as a two-dimensional array (color, anticolor).

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      function gen_particle_flow (prt_obj, code_index) result (code) bind(C)
        import
        integer(c_int) :: code
        type(c_ptr), value :: prt_obj
        integer(c_int), value :: code_index
      end function gen_particle_flow
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_particle_get_color
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_particle_get_color (prt) result (col)
      integer, dimension(2) :: col
      type(hepmc_particle_t), intent(in) :: prt
      col(1) = gen_particle_flow (prt%obj, 1)
      col(2) = - gen_particle_flow (prt%obj, 2)
    end function hepmc_particle_get_color
```

19.8.5 GenVertex

Vertices are made of particles (incoming and outgoing).

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_t
```

⟨*HepMC interface: types*⟩+≡
```
    type :: hepmc_vertex_t
      private
      type(c_ptr) :: obj
    end type hepmc_vertex_t
```

Constructor. Two versions, one plain, one with the position in space and time (measured in mm) as argument. The Fortran version has initializer form, and the vertex position is an optional argument.

A destructor is unnecessary as long as all vertices are entered into an event container.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       type(c_ptr) function new_gen_vertex () bind(C)
         import
       end function new_gen_vertex
    end interface
    interface
       type(c_ptr) function new_gen_vertex_pos (prt_obj) bind(C)
         import
         type(c_ptr), value :: prt_obj
       end function new_gen_vertex_pos
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_init
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_vertex_init (v, x)
      type(hepmc_vertex_t), intent(out) :: v
      type(vector4_t), intent(in), optional :: x
      type(hepmc_four_vector_t) :: pos
      if (present (x)) then
         call hepmc_four_vector_init (pos, x)
         v%obj = new_gen_vertex_pos (pos%obj)
         call hepmc_four_vector_final (pos)
      else
         v%obj = new_gen_vertex ()
      end if
    end subroutine hepmc_vertex_init
```

Return true if the vertex pointer is non-null:

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       function gen_vertex_is_valid (v_obj) result (flag) bind(C)
         import
         logical(c_bool) :: flag
         type(c_ptr), value :: v_obj
       end function gen_vertex_is_valid
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_is_valid
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_vertex_is_valid (v) result (flag)
      logical :: flag
      type(hepmc_vertex_t), intent(in) :: v
      flag = gen_vertex_is_valid (v%obj)
    end function hepmc_vertex_is_valid
```

Add a particle to a vertex, incoming or outgoing.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
```

2635

```
    subroutine gen_vertex_add_particle_in (v_obj, prt_obj) bind(C)
      import

```

```
function hepmc_vertex_get_n_out (v) result (n_out)
  integer :: n_out
  type(hepmc_vertex_t), intent(in) :: v
  n_out = gen_vertex_particles_out_size (v%obj)
end function hepmc_vertex_get_n_out
```

19.8.6 Vertex-particle-in iterator

This iterator iterates over all incoming particles in an vertex. We store a pointer to the vertex in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_in_iterator_t
```

⟨*HepMC interface: types*⟩+≡
```
    type :: hepmc_vertex_particle_in_iterator_t
      private
      type(c_ptr) :: obj
      type(c_ptr) :: v_obj
    end type hepmc_vertex_particle_in_iterator_t
```

Constructor. The iterator is initialized at the first particle in the vertex.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      type(c_ptr) function &
          new_vertex_particles_in_const_iterator (v_obj) bind(C)
        import
        type(c_ptr), value :: v_obj
      end function new_vertex_particles_in_const_iterator
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_in_iterator_init
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_vertex_particle_in_iterator_init (it, v)
      type(hepmc_vertex_particle_in_iterator_t), intent(out) :: it
      type(hepmc_vertex_t), intent(in) :: v
      it%obj = new_vertex_particles_in_const_iterator (v%obj)
      it%v_obj = v%obj
    end subroutine hepmc_vertex_particle_in_iterator_init
```

Destructor. Necessary because the iterator is allocated on the heap.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      subroutine vertex_particles_in_const_iterator_delete (it_obj) bind(C)
        import
        type(c_ptr), value :: it_obj
      end subroutine vertex_particles_in_const_iterator_delete
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_in_iterator_final
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_vertex_particle_in_iterator_final (it)
      type(hepmc_vertex_particle_in_iterator_t), intent(inout) :: it
      call vertex_particles_in_const_iterator_delete (it%obj)
    end subroutine hepmc_vertex_particle_in_iterator_final
```

Increment

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      subroutine vertex_particles_in_const_iterator_advance (it_obj) bind(C)
        import
        type(c_ptr), value :: it_obj
      end subroutine vertex_particles_in_const_iterator_advance
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_in_iterator_advance
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_vertex_particle_in_iterator_advance (it)
      type(hepmc_vertex_particle_in_iterator_t), intent(inout) :: it
      call vertex_particles_in_const_iterator_advance (it%obj)
    end subroutine hepmc_vertex_particle_in_iterator_advance
```

Reset to the beginning

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      subroutine vertex_particles_in_const_iterator_reset &
          (it_obj, v_obj) bind(C)
        import
        type(c_ptr), value :: it_obj, v_obj
      end subroutine vertex_particles_in_const_iterator_reset
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_in_iterator_reset
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_vertex_particle_in_iterator_reset (it)
      type(hepmc_vertex_particle_in_iterator_t), intent(inout) :: it
      call vertex_particles_in_const_iterator_reset (it%obj, it%v_obj)
    end subroutine hepmc_vertex_particle_in_iterator_reset
```

Test: return true as long as we are not past the end.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      function vertex_particles_in_const_iterator_is_valid &
          (it_obj, v_obj) result (flag) bind(C)
        import
        logical(c_bool) :: flag
        type(c_ptr), value :: it_obj, v_obj
      end function vertex_particles_in_const_iterator_is_valid
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_in_iterator_is_valid
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_vertex_particle_in_iterator_is_valid (it) result (flag)
      logical :: flag
      type(hepmc_vertex_particle_in_iterator_t), intent(in) :: it
      flag = vertex_particles_in_const_iterator_is_valid (it%obj, it%v_obj)
    end function hepmc_vertex_particle_in_iterator_is_valid
```

Return the particle pointed to by the iterator. (The particle object should not be finalized, since it contains merely a pointer to the particle which is owned by the vertex.)

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      type(c_ptr) function &
          vertex_particles_in_const_iterator_get (it_obj) bind(C)
        import
        type(c_ptr), value :: it_obj
      end function vertex_particles_in_const_iterator_get
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_in_iterator_get
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_vertex_particle_in_iterator_get (it) result (prt)
      type(hepmc_particle_t) :: prt
      type(hepmc_vertex_particle_in_iterator_t), intent(in) :: it
      prt%obj = vertex_particles_in_const_iterator_get (it%obj)
    end function hepmc_vertex_particle_in_iterator_get
```

19.8.7 Vertex-particle-out iterator

This iterator iterates over all incoming particles in an vertex. We store a pointer to the vertex in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_out_iterator_t
```

⟨*HepMC interface: types*⟩+≡
```
    type :: hepmc_vertex_particle_out_iterator_t
      private
      type(c_ptr) :: obj
      type(c_ptr) :: v_obj
    end type hepmc_vertex_particle_out_iterator_t
```

Constructor. The iterator is initialized at the first particle in the vertex.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      type(c_ptr) function &
          new_vertex_particles_out_const_iterator (v_obj) bind(C)
        import
```

```
      type(c_ptr), value :: v_obj
    end function new_vertex_particles_out_const_iterator
  end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_out_iterator_init
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_vertex_particle_out_iterator_init (it, v)
      type(hepmc_vertex_particle_out_iterator_t), intent(out) :: it
      type(hepmc_vertex_t), intent(in) :: v
      it%obj = new_vertex_particles_out_const_iterator (v%obj)
      it%v_obj = v%obj
    end subroutine hepmc_vertex_particle_out_iterator_init
```

Destructor. Necessary because the iterator is allocated on the heap.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      subroutine vertex_particles_out_const_iterator_delete (it_obj) bind(C)
        import
        type(c_ptr), value :: it_obj
      end subroutine vertex_particles_out_const_iterator_delete
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_out_iterator_final
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_vertex_particle_out_iterator_final (it)
      type(hepmc_vertex_particle_out_iterator_t), intent(inout) :: it
      call vertex_particles_out_const_iterator_delete (it%obj)
    end subroutine hepmc_vertex_particle_out_iterator_final
```

Increment

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      subroutine vertex_particles_out_const_iterator_advance (it_obj) bind(C)
        import
        type(c_ptr), value :: it_obj
      end subroutine vertex_particles_out_const_iterator_advance
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_out_iterator_advance
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_vertex_particle_out_iterator_advance (it)
      type(hepmc_vertex_particle_out_iterator_t), intent(inout) :: it
      call vertex_particles_out_const_iterator_advance (it%obj)
    end subroutine hepmc_vertex_particle_out_iterator_advance
```

Reset to the beginning

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      subroutine vertex_particles_out_const_iterator_reset &
```

```
          (it_obj, v_obj) bind(C)
        import
        type(c_ptr), value :: it_obj, v_obj
      end subroutine vertex_particles_out_const_iterator_reset
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_out_iterator_reset
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_vertex_particle_out_iterator_reset (it)
      type(hepmc_vertex_particle_out_iterator_t), intent(inout) :: it
      call vertex_particles_out_const_iterator_reset (it%obj, it%v_obj)
    end subroutine hepmc_vertex_particle_out_iterator_reset
```

Test: return true as long as we are not past the end.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      function vertex_particles_out_const_iterator_is_valid &
           (it_obj, v_obj) result (flag) bind(C)
        import
        logical(c_bool) :: flag
        type(c_ptr), value :: it_obj, v_obj
      end function vertex_particles_out_const_iterator_is_valid
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_out_iterator_is_valid
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_vertex_particle_out_iterator_is_valid (it) result (flag)
      logical :: flag
      type(hepmc_vertex_particle_out_iterator_t), intent(in) :: it
      flag = vertex_particles_out_const_iterator_is_valid (it%obj, it%v_obj)
    end function hepmc_vertex_particle_out_iterator_is_valid
```

Return the particle pointed to by the iterator. (The particle object should not
be finalized, since it contains merely a pointer to the particle which is owned by
the vertex.)

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      type(c_ptr) function &
           vertex_particles_out_const_iterator_get (it_obj) bind(C)
        import
        type(c_ptr), value :: it_obj
      end function vertex_particles_out_const_iterator_get
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_vertex_particle_out_iterator_get
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_vertex_particle_out_iterator_get (it) result (prt)
      type(hepmc_particle_t) :: prt
      type(hepmc_vertex_particle_out_iterator_t), intent(in) :: it
      prt%obj = vertex_particles_out_const_iterator_get (it%obj)
```

```
        end function hepmc_vertex_particle_out_iterator_get
```

19.8.8   GenEvent

The main object of HepMC is a GenEvent. The object is filled by GenVertex objects, which in turn contain GenParticle objects.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_t
```

⟨*HepMC interface: types*⟩+≡
```
    type :: hepmc_event_t
       private
       type(c_ptr) :: obj
    end type hepmc_event_t
```

Constructor. Arguments are process ID (integer) and event ID (integer).
The Fortran version has initializer form.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       type(c_ptr) function new_gen_event (proc_id, event_id) bind(C)
         import
         integer(c_int), value :: proc_id, event_id
       end function new_gen_event
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_init
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_init (evt, proc_id, event_id)
      type(hepmc_event_t), intent(out) :: evt
      integer, intent(in), optional :: proc_id, event_id
      integer(c_int) :: pid, eid
      pid = 0;  if (present (proc_id))  pid = proc_id
      eid = 0;  if (present (event_id)) eid = event_id
      evt%obj = new_gen_event (pid, eid)
    end subroutine hepmc_event_init
```

Destructor.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       subroutine gen_event_delete (evt_obj) bind(C)
         import
         type(c_ptr), value :: evt_obj
       end subroutine gen_event_delete
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_final
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_final (evt)
      type(hepmc_event_t), intent(inout) :: evt
      call gen_event_delete (evt%obj)
    end subroutine hepmc_event_final
```

Screen output. Printing to file is possible in principle (using a C++ output channel), by allowing an argument. Printing to an open Fortran unit is obviously not possible.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       subroutine gen_event_print (evt_obj) bind(C)
         import
         type(c_ptr), value :: evt_obj
       end subroutine gen_event_print
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_print
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_print (evt)
      type(hepmc_event_t), intent(in) :: evt
      call gen_event_print (evt%obj)
    end subroutine hepmc_event_print
```

Get the event number.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       integer(c_int) function gen_event_event_number (evt_obj) bind(C)
         use iso_c_binding !NODEP!
         type(c_ptr), value :: evt_obj
       end function gen_event_event_number
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_get_event_index
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_event_get_event_index (evt) result (i_proc)
      integer :: i_proc
      type(hepmc_event_t), intent(in) :: evt
      i_proc = gen_event_event_number (evt%obj)
    end function hepmc_event_get_event_index
```

Set the numeric signal process ID

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       subroutine gen_event_set_signal_process_id (evt_obj, proc_id) bind(C)
         import
         type(c_ptr), value :: evt_obj
         integer(c_int), value :: proc_id
       end subroutine gen_event_set_signal_process_id
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_set_process_id
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_set_process_id (evt, proc)
      type(hepmc_event_t), intent(in) :: evt
      integer, intent(in) :: proc
      integer(c_int) :: i_proc
      i_proc = proc
      call gen_event_set_signal_process_id (evt%obj, i_proc)
    end subroutine hepmc_event_set_process_id
```

Get the numeric signal process ID

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      integer(c_int) function gen_event_signal_process_id (evt_obj) bind(C)
        import
        type(c_ptr), value :: evt_obj
      end function gen_event_signal_process_id
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_get_process_id
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_event_get_process_id (evt) result (i_proc)
      integer :: i_proc
      type(hepmc_event_t), intent(in) :: evt
      i_proc = gen_event_signal_process_id (evt%obj)
    end function hepmc_event_get_process_id
```

Set the event energy scale

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      subroutine gen_event_set_event_scale (evt_obj, scale) bind(C)
        import
        type(c_ptr), value :: evt_obj
        real(c_double), value :: scale
      end subroutine gen_event_set_event_scale
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_set_scale
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_set_scale (evt, scale)
      type(hepmc_event_t), intent(in) :: evt
      real(default), intent(in) :: scale
      real(c_double) :: cscale
      cscale = scale
      call gen_event_set_event_scale (evt%obj, cscale)
    end subroutine hepmc_event_set_scale
```

Get the event energy scale

⟨HepMC interface: interfaces⟩+≡
```
    interface
       real(c_double) function gen_event_event_scale (evt_obj) bind(C)
         import
         type(c_ptr), value :: evt_obj
       end function gen_event_event_scale
    end interface
```

⟨HepMC interface: public⟩+≡
```

       end function gen_event_weight
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_get_weight
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_event_get_weight (evt, index) result (weight)
      real(default) :: weight
      type(hepmc_event_t), intent(in) :: evt
      integer, intent(in) :: index
      integer(c_int) :: i
      i = index - 1
      weight = gen_event_weight (evt%obj, i)
    end function hepmc_event_get_weight
```

Add a vertex to the event container.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       subroutine gen_event_add_vertex (evt_obj, v_obj) bind(C)
         import
         type(c_ptr), value :: evt_obj
         type(c_ptr), value :: v_obj
       end subroutine gen_event_add_vertex
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_add_vertex
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_add_vertex (evt, v)
      type(hepmc_event_t), intent(inout) :: evt
      type(hepmc_vertex_t), intent(in) :: v
      call gen_event_add_vertex (evt%obj, v%obj)
    end subroutine hepmc_event_add_vertex
```

Mark a particular vertex as the signal process (hard interaction).

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       subroutine gen_event_set_signal_process_vertex (evt_obj, v_obj) bind(C)
         import
         type(c_ptr), value :: evt_obj
         type(c_ptr), value :: v_obj
       end subroutine gen_event_set_signal_process_vertex
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_set_signal_process_vertex
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_set_signal_process_vertex (evt, v)
      type(hepmc_event_t), intent(inout) :: evt
      type(hepmc_vertex_t), intent(in) :: v
      call gen_event_set_signal_process_vertex (evt%obj, v%obj)
    end subroutine hepmc_event_set_signal_process_vertex
```

Set the beam particles explicitly.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_set_beam_particles
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_set_beam_particles (evt, prt1, prt2)
      type(hepmc_event_t), intent(inout) :: evt
      type(hepmc_particle_t), intent(in) :: prt1, prt2
      logical(c_bool) :: flag
      flag = gen_event_set_beam_particles (evt%obj, prt1%obj, prt2%obj)
    end subroutine hepmc_event_set_beam_particles
```

The C function returns a boolean which we do not use.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       logical(c_bool) function gen_event_set_beam_particles &
            (evt_obj, prt1_obj, prt2_obj) bind(C)
         import
         type(c_ptr), value :: evt_obj, prt1_obj, prt2_obj
       end function gen_event_set_beam_particles
    end interface
```

Set the cross section and error explicitly. Note that HepMC uses pb, while WHIZARD uses fb.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_set_cross_section
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_set_cross_section (evt, xsec, xsec_err)
      type(hepmc_event_t), intent(inout) :: evt
      real(default), intent(in) :: xsec, xsec_err
      call gen_event_set_cross_section &
           (evt%obj, &
           real (xsec * 1e-3_default, c_double), &
           real (xsec_err * 1e-3_default, c_double))
    end subroutine hepmc_event_set_cross_section
```

The C function returns a boolean which we do not use.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       subroutine gen_event_set_cross_section (evt_obj, xs, xs_err) bind(C)
         import
         type(c_ptr), value :: evt_obj
         real(c_double), value :: xs, xs_err
       end subroutine gen_event_set_cross_section
```

```
    end interface
```

19.8.9 Event-particle iterator

This iterator iterates over all particles in an event. We store a pointer to the event in addition to the iterator. This allows for simple end checking.

The iterator is actually a constant iterator; it can only read.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_particle_iterator_t
```

⟨*HepMC interface: types*⟩+≡
```
    type :: hepmc_event_particle_iterator_t
       private
       type(c_ptr) :: obj
       type(c_ptr) :: evt_obj
    end type hepmc_event_particle_iterator_t
```

Constructor. The iterator is initialized at the first particle in the event.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       type(c_ptr) function new_event_particle_const_iterator (evt_obj) bind(C)
         import
         type(c_ptr), value :: evt_obj
       end function new_event_particle_const_iterator
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_particle_iterator_init
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_particle_iterator_init (it, evt)
      type(hepmc_event_particle_iterator_t), intent(out) :: it
      type(hepmc_event_t), intent(in) :: evt
      it%obj = new_event_particle_const_iterator (evt%obj)
      it%evt_obj = evt%obj
    end subroutine hepmc_event_particle_iterator_init
```

Destructor. Necessary because the iterator is allocated on the heap.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       subroutine event_particle_const_iterator_delete (it_obj) bind(C)
         import
         type(c_ptr), value :: it_obj
       end subroutine event_particle_const_iterator_delete
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_particle_iterator_final
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_event_particle_iterator_final (it)
      type(hepmc_event_particle_iterator_t), intent(inout) :: it
      call event_particle_const_iterator_delete (it%obj)
    end subroutine hepmc_event_particle_iterator_final
```

Increment

⟨HepMC interface: interfaces⟩+≡
```
    interface
       subroutine event_particle_const_iterator_advance (it_obj) bind(C)
         import
         type(c_ptr), value :: it_obj
       end subroutine event_particle_const_iterator_advance
    end interface
```

⟨HepMC interface: public⟩+≡
```
    public :: hepmc_event_particle_iterator_advance
```

⟨HepMC interface: procedures⟩+≡
```
    subroutine hepmc_event_particle_iterator_advance (it)
      type(hepmc_event_particle_iterator_t), intent(inout) :: it
      call event_particle_const_iterator_advance (it%obj)
    end subroutine hepmc_event_particle_iterator_advance
```

Reset to the beginning

⟨HepMC interface: interfaces⟩+≡
```
    interface
       subroutine event_particle_const_iterator_reset (it_obj, evt_obj) bind(C)
         import
         type(c_ptr), value :: it_obj, evt_obj
       end subroutine event_particle_const_iterator_reset
    end interface
```

⟨HepMC interface: public⟩+≡
```
    public :: hepmc_event_particle_iterator_reset
```

⟨HepMC interface: procedures⟩+≡
```
    subroutine hepmc_event_particle_iterator_reset (it)
      type(hepmc_event_particle_iterator_t), intent(inout) :: it
      call event_particle_const_iterator_reset (it%obj, it%evt_obj)
    end subroutine hepmc_event_particle_iterator_reset
```

Test: return true as long as we are not past the end.

⟨HepMC interface: interfaces⟩+≡
```
    interface
       function event_particle_const_iterator_is_valid &
            (it_obj, evt_obj) result (flag) bind(C)
         import
         logical(c_bool) :: flag
         type(c_ptr), value :: it_obj, evt_obj
       end function event_particle_const_iterator_is_valid
    end interface
```

⟨HepMC interface: public⟩+≡
```
    public :: hepmc_event_particle_iterator_is_valid
```

⟨HepMC interface: procedures⟩+≡
```
    function hepmc_event_particle_iterator_is_valid (it) result (flag)
      logical :: flag
      type(hepmc_event_particle_iterator_t), intent(in) :: it
      flag = event_particle_const_iterator_is_valid (it%obj, it%evt_obj)
    end function hepmc_event_particle_iterator_is_valid
```

Return the particle pointed to by the iterator. (The particle object should not be finalized, since it contains merely a pointer to the particle which is owned by the vertex.)

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       type(c_ptr) function event_particle_const_iterator_get (it_obj) bind(C)
         import
         type(c_ptr), value :: it_obj
       end function event_particle_const_iterator_get
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_event_particle_iterator_get
```

⟨*HepMC interface: procedures*⟩+≡
```
    function hepmc_event_particle_iterator_get (it) result (prt)
      type(hepmc_particle_t) :: prt
      type(hepmc_event_particle_iterator_t), intent(in) :: it
      prt%obj = event_particle_const_iterator_get (it%obj)
    end function hepmc_event_particle_iterator_get
```

19.8.10 I/O streams

There is a specific I/O stream type for handling the output of GenEvent objects (i.e., Monte Carlo event samples) to file. Opening the file is done by the constructor, closing by the destructor.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_iostream_t
```

⟨*HepMC interface: types*⟩+≡
```
    type :: hepmc_iostream_t
       private
       type(c_ptr) :: obj
    end type hepmc_iostream_t
```

Constructor for an output stream associated to a file.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
       type(c_ptr) function new_io_gen_event_out (filename) bind(C)
         import
         character(c_char), dimension(*), intent(in) :: filename
       end function new_io_gen_event_out
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_iostream_open_out
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_iostream_open_out (iostream, filename)
      type(hepmc_iostream_t), intent(out) :: iostream
      type(string_t), intent(in) :: filename
      iostream%obj = new_io_gen_event_out (char (filename) // c_null_char)
    end subroutine hepmc_iostream_open_out
```

Constructor for an input stream associated to a file.

⟨*HepMC interface: interfaces*⟩+≡
```
interface
   type(c_ptr) function new_io_gen_event_in (filename) bind(C)
     import
     character(c_char), dimension(*), intent(in) :: filename
   end function new_io_gen_event_in
end interface
```

⟨*HepMC interface: public*⟩+≡
```
public :: hepmc_iostream_open_in
```

⟨*HepMC interface: procedures*⟩+≡
```
subroutine hepmc_iostream_open_in (iostream, filename)
  type(hepmc_iostream_t), intent(out) :: iostream
  type(string_t), intent(in) :: filename
  iostream%obj = new_io_gen_event_in (char (filename) // c_null_char)
end subroutine hepmc_iostream_open_in
```

Destructor:

⟨*HepMC interface: interfaces*⟩+≡
```
interface
   subroutine io_gen_event_delete (io_obj) bind(C)
     import
     type(c_ptr), value :: io_obj
   end subroutine io_gen_event_delete
end interface
```

⟨*HepMC interface: public*⟩+≡
```
public :: hepmc_iostream_close
```

⟨*HepMC interface: procedures*⟩+≡
```
subroutine hepmc_iostream_close (iostream)
  type(hepmc_iostream_t), intent(inout) :: iostream
  call io_gen_event_delete (iostream%obj)
end subroutine hepmc_iostream_close
```

Write a single event to the I/O stream.

⟨*HepMC interface: interfaces*⟩+≡
```
interface
   subroutine io_gen_event_write_event (io_obj, evt_obj) bind(C)
     import
     type(c_ptr), value :: io_obj, evt_obj
   end subroutine io_gen_event_write_event
end interface
```

⟨*HepMC interface: public*⟩+≡
```
public :: hepmc_iostream_write_event
```

⟨*HepMC interface: procedures*⟩+≡
```
subroutine hepmc_iostream_write_event (iostream, evt)
  type(hepmc_iostream_t), intent(inout) :: iostream
  type(hepmc_event_t), intent(in) :: evt
  call io_gen_event_write_event (iostream%obj, evt%obj)
end subroutine hepmc_iostream_write_event
```

Read a single event from the I/O stream. Return true if successful.

⟨*HepMC interface: interfaces*⟩+≡
```
    interface
      logical(c_bool) function io_gen_event_read_event (io_obj, evt_obj) bind(C)
        import
        type(c_ptr), value :: io_obj, evt_obj
      end function io_gen_event_read_event
    end interface
```

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_iostream_read_event
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_iostream_read_event (iostream, evt, ok)
      type(hepmc_iostream_t), intent(inout) :: iostream
      type(hepmc_event_t), intent(in) :: evt
      logical, intent(out) :: ok
      ok = io_gen_event_read_event (iostream%obj, evt%obj)
    end subroutine hepmc_iostream_read_event
```

19.8.11 Unit tests

This test example is an abridged version from the build-from-scratch example in the HepMC distribution. We create two vertices for $p \to q$ PDF splitting, then a vertex for a $qq \to W^- g$ hard-interaction process, and finally a vertex for $W^- \to qq$ decay. The setup is for LHC kinematics.

Extending the original example, we set color flow for the incoming quarks and polarization for the outgoing photon. For the latter, we have to define a particle-data object for the photon, so a flavor object can be correctly initialized.

⟨*HepMC interface: public*⟩+≡
```
    public :: hepmc_test
```

⟨*HepMC interface: procedures*⟩+≡
```
    subroutine hepmc_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
```
⟨*HepMC interface: execute tests*⟩
```
    end subroutine hepmc_test
```

⟨*HepMC interface: execute tests*⟩≡

19.11   STDHEP File Formats

Here, we implement the two existing STDHEP file formats, one based on the
HEPRUP/HEPEUP common blocks, the other based on the HEPEVT common
block. The second one is actually the standard STDHEP format.

⟨eio_stdhep.f90⟩≡
  ⟨*File header*⟩

  module eio_stdhep

    use kinds !NODEP!
  ⟨*Use file utils*⟩
  ⟨*Use strings*⟩
    use diagnostics !NODEP!
    use unit_tests
```

```
      use lorentz !NODEP!
      use models
      use particles
      use beams
      use processes
      use events
      use eio_data
      use eio_base
      use hep_common
      use hep_events
```

⟨*Standard module head*⟩

⟨*EIO stdhep: public*⟩

⟨*EIO stdhep: types*⟩

⟨*EIO stdhep: variables*⟩

```
contains
```

⟨*EIO stdhep: procedures*⟩

⟨*EIO stdhep: tests*⟩

```
end module eio_stdhep
```

19.11.1   Type

⟨*EIO stdhep: public*⟩≡
```
      public :: eio_stdhep_t
```

⟨*EIO stdhep: types*⟩≡
```
      type, abstract, extends (eio_t) :: eio_stdhep_t
         logical :: writing = .false.
         integer :: unit = 0
         logical :: keep_beams = .false.
         integer(i64) :: n_events_expected = 0
       contains
       ⟨EIO stdhep: eio stdhep: TBP⟩
      end type eio_stdhep_t
```

⟨*EIO stdhep: public*⟩+≡
```
      public :: eio_stdhep_hepevt_t
```

⟨*EIO stdhep: types*⟩+≡
```
      type, extends (eio_stdhep_t) :: eio_stdhep_hepevt_t
      end type eio_stdhep_hepevt_t
```

⟨*EIO stdhep: public*⟩+≡
```
      public :: eio_stdhep_hepeup_t
```

⟨*EIO stdhep: types*⟩+≡
```
type, extends (eio_stdhep_t) :: eio_stdhep_hepeup_t
end type eio_stdhep_hepeup_t
```

19.11.2   Specific Methods

Set parameters that are specifically used with STDHEP file formats.

⟨*EIO stdhep: eio stdhep: TBP*⟩≡
```
procedure :: set_parameters => eio_stdhep_set_parameters
```

⟨*EIO stdhep: procedures*⟩≡
```
subroutine eio_stdhep_set_parameters (eio, keep_beams, extension)
  class(eio_stdhep_t), intent(inout) :: eio
  logical, intent(in), optional :: keep_beams
  type(string_t), intent(in), optional :: extension
  if (present (keep_beams))  eio%keep_beams = keep_beams
  if (present (extension)) then
     eio%extension = extension
  else
     select type (eio)
     type is (eio_stdhep_hepevt_t)
        eio%extension = "stdhep"
     type is (eio_stdhep_hepeup_t)
        eio%extension = "up.stdhep"
     end select
  end if
end subroutine eio_stdhep_set_parameters
```

19.11.3   Common Methods

Output. This is not the actual event format, but a readable account of the current object status.

⟨*EIO stdhep: eio stdhep: TBP*⟩+≡
```
procedure :: write => eio_stdhep_write
```

⟨*EIO stdhep: procedures*⟩+≡
```
subroutine eio_stdhep_write (object, unit)
  class(eio_stdhep_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u
  u = output_unit (unit)
  write (u, "(1x,A)")  "STDHEP event stream:"
  if (object%writing) then
     write (u, "(3x,A,A)")  "Writing to file  = ", char (object%filename)
  else
     write (u, "(3x,A)")  "[closed]"
  end if
  write (u, "(3x,A,L1)")    "Keep beams       = ", object%keep_beams
end subroutine eio_stdhep_write
```

Finalizer: close any open file.

⟨*EIO stdhep: eio stdhep: TBP*⟩+≡
```
    procedure :: final => eio_stdhep_final
```

⟨*EIO stdhep: procedures*⟩+≡
```
    subroutine eio_stdhep_final (object)
      class(eio_stdhep_t), intent(inout) :: object
      if (object%writing) then
         write (msg_buffer, "(A,A,A)")  "Events: closing STDHEP file '", &
               char (object%filename), "'"
         call msg_message ()
         call stdhep_end
         object%writing = .false.
      end if
    end subroutine eio_stdhep_final
```

Split event file: increment the counter, close the current file, open a new one. If
the file needs a header, repeat it for the new file. (We assume that the common
block contents are still intact.)

⟨*EIO stdhep: eio stdhep: TBP*⟩+≡
```
    procedure :: split_out => eio_stdhep_split_out
```

⟨*EIO stdhep: procedures*⟩+≡
```
    subroutine eio_stdhep_split_out (eio)
      class(eio_stdhep_t), intent(inout) :: eio
      if (eio%split) then
         eio%split_index = eio%split_index + 1
         call eio%set_filename ()

19.12   Event Weight Output

This is an output-only format. For each event, we print the indices that identify
process, process part (MCI group), and term. As numerical information we print
the squared matrix element (trace) and the event weight.

      if (present (success))  success = .false.
    end subroutine eio_weights_switch_inout
```

Output an event. Write first the event indices, then weight and two values of the squared matrix element: `sqme_ref` is the value stored in the event record, and `sqme_prc` is the one stored in the process instance. (They can differ: when recalculating, the former is read from file and the latter is the result of the new calculation.)

For the alternative entries, the `sqme` value is always obtained by a new calculation, and thus qualifies as `sqme_prc`.

⟨*EIO weights: eio weights: TBP*⟩+≡

Chapter 20

The SUSY Les Houches Accord

The SUSY Les Houches Accord defines a standard interfaces for storing the physics data of SUSY models. Here, we provide the means for reading, storing, and writing such data.

⟨slha_interface.f90⟩≡

20.0.5   Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

⟨*SLHA: parameters*⟩≡

```
    integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2
```

⟨*SLHA: procedures*⟩≡

```
  subroutine slha_preprocess (stream, ifile)
    type(stream_t), intent(inout), target :: stream
    type(ifile_t), intent(out) :: ifile
    type(string_t) :: buffer, line, item
    integer :: iostat
    integer :: mode
    mode = MODE
    SCAN_FILE: do
       call stream_get_record (stream, buffer, iostat)
       select case (iostat)
       case (0)
          call split (buffer, line, "#")
          if (len_trim (line) == 0)  cycle SCAN_FILE
          select case (char (extract (line, 1, 1)))
          case ("B", "b")
             mode = check_block_handling (line)
             call ifile_append (ifile, line // "$")
          case ("D", "d")
             mode = MODE_DATA
             call ifile_append (ifile, line // "$")
          case (" ")
             select case (mode)
             case (MODE_DATA)
                call ifile_append (ifile, "DATA" // line // "$")
             case (MODE_INFO)
                line = adjustl (line)
                call split (line, item, " ")
```

```
              call ifile_append (ifile, "INFO" // " " // item // " " &
                   // '"' // trim (adjustl (line)) // '" $')
           end select
        case default
           call msg_message (char (line))
           call msg_fatal ("SLHA: Incomprehensible line")
        end select
     case (EOF)
        exit SCAN_FILE
     case default
        call msg_fatal ("SLHA: I/O error occured while reading SLHA input")
     end select
  end do SCAN_FILE
end subroutine slha_preprocess
```

Return the mode that we should treat this block with. We need to recognize only those blocks that we actually use.

⟨*SLHA: procedures*⟩+≡
```
function check_block_handling (line) result (mode)
  integer :: mode
  type(string_t), intent(in) :: line
  type(string_t) :: buffer, key, block_name

      call ifile_append (ifile, "INT integer")
      call ifile_append (ifile, "KEY '-'")
      call ifile_append (ifile, "KEY '+'")
      call ifile_append (ifile, "SEQ block_info = INFO info_line '$'")
```

```
      call ifile_append (ifile, "KEY INFO")
      call ifile_append (ifile, "SEQ info_line = integer string_literal")
      call ifile_append (ifile, "QUO string_literal = '""'...'""'")
      call ifile_append (ifile, "SEQ decay_def = " &
           // "DECAY decay_spec '$' decay_data*")
      call ifile_append (ifile, "KEY DECAY")
      call ifile_append (ifile, "SEQ decay_spec = pdg_code data_item")
      call ifile_append (ifile, "ALT pdg_code = signed_integer | integer")
      call ifile_append (ifile, "SEQ signed_integer = sign integer")
      call ifile_append (ifile, "SEQ decay_data = DATA decay_line '$'")
      call ifile_append (ifile, "SEQ decay_line = data_item integer pdg_code+")
    end subroutine define_slha_syntax
```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

⟨*SLHA: public*⟩+≡
```
    public :: lexer_init_slha
```

⟨*SLHA: procedures*⟩+≡
```
    subroutine lexer_init_slha (lexer)
      type(lexer_t), intent(out) :: lexer
      call lexer_init (lexer, &
           comment_chars = "#", &
           quote_chars = '"', &
           quote_match = '"', &
           single_chars = "+-=$", &
           special_class = [ "" ], &
           keyword_list = syntax_get_keyword_list_ptr (syntax_slha), &
           upper_case_keywords = .true.)  ! $
    end subroutine lexer_init_slha
```

20.0.7   Interpreter

Find blocks

From the parse tree, find the node that represents a particular block. If `required` is true, issue an error if not found. Since `block_name` is always invoked with capital letters, we have to capitalize `pn_block_name`.

⟨*SLHA: procedures*⟩+≡
```
    function slha_get_block_ptr &
         (parse_tree, block_name, required) result (pn_block)
      type(parse_node_t), pointer :: pn_block
      type(parse_tree_t), intent(in) :: parse_tree
      type(string_t), intent(in) :: block_name
      logical, intent(in) :: required
      type(parse_node_t), pointer :: pn_root, pn_block_spec, pn_block_name
      pn_root => parse_tree_get_root_ptr (parse_tree)
      pn_block => parse_node_get_sub_ptr (pn_root)
      do while (associated (pn_block))
         select case (char (parse_node_get_rule_key (pn_block)))
```

```
         case ("block_def")
            pn_block_spec => parse_node_get_sub_ptr (pn_block, 2)
            pn_block_name => parse_node_get_sub_ptr (pn_block_spec)
            if (trim (adjustl (upper_case (parse_node_get_string &
                     (pn_block_name)))) == block_name) then
               return
            end if
         end select
         pn_block => parse_node_get_next_ptr (pn_block)
      end do
      if (required) then
         call msg_fatal ("SLHA: block '" // char (block_name) // "' not found")
      end if
    end function slha_get_block_ptr
```

Scan the file for the first/next DECAY block.

⟨*SLHA: procedures*⟩+≡

```
    function slha_get_first_decay_ptr (parse_tree) result (pn_decay)
      type(parse_node_t), pointer :: pn_decay
      type(parse_tree_t), intent(in) :: parse_tree
      type(parse_node_t), pointer :: pn_root
      pn_root => parse_tree_get_root_ptr (parse_tree)
      pn_decay => parse_node_get_sub_ptr (pn_root)
      do while (associated (pn_decay))
         select case (char (parse_node_get_rule_key (pn_decay)))
         case ("decay_def")
            return
         end select
         pn_decay => parse_node_get_next_ptr (pn_decay)
      end do
    end function slha_get_first_decay_ptr

    function slha_get_next_decay_ptr (pn_block) result (pn_decay)
      type(parse_node_t), pointer :: pn_decay
      type(parse_node_t), intent(in), target :: pn_block
      pn_decay => parse_node_get_next_ptr (pn_block)

         pn_data => parse_node_get_next_ptr (pn_data)
      end do
      pn_item => null ()
   end subroutine slha_next_index_pair_ptr
```

Handle info data

Return all strings with index `i`. The result is an allocated string array. Since
we do not know the number of matching entries in advance, we build an inter-
mediate list which is transferred to the final array and deleted before exiting.

⟨*SLHA: procedures*⟩+≡

```
   subroutine retrieve_strings_in_block (pn_block, code, str_array)
      type(parse_node_t), intent(in), target :: pn_block
      integer, intent(in) :: code
      type(string_t), dimension(:), allocatable, intent(out) :: str_array
      type(parse_node_t), pointer :: pn_data, pn_item
      type :: str_entry_t
         type(string_t) :: str
         type(str_entry_t), pointer :: next => null ()
      end type str_entry_t
      type(str_entry_t), pointer :: first => null ()
      type(str_entry_t), pointer :: current => null ()
      integer :: n
      n = 0
      call slha_find_index_ptr (pn_block, pn_data, pn_item, code)
      if (associated (pn_item)) then
         n = n + 1
         allocate (first)
         first%str = parse_node_get_string (pn_item)
         current => first
         do while (associated (pn_data))
            pn_data => parse_node_get_next_ptr (pn_data)
            call slha_next_index_ptr (pn_data, pn_item, code)
            if (associated (pn_item)) then
               n = n + 1
               allocate (current%next)
               current => current%next
               current%str = parse_node_get_string (pn_item)
            end if
```

```
         end do
         allocate (str_array (n))
         n = 0
         do while (associated (first))
            n = n + 1
            current => first
            str_array(n) = current%str
            first => first%next
            deallocate (current)
         end do
      else
         allocate (str_array (0))
      end if
   end subroutine retrieve_strings_in_block
```

Transfer data from SLHA to variables

Extract real parameter with index i. If it does not exist, retrieve it from the variable list, using the given name.

⟨*SLHA: procedures*⟩+≡
```
   function get_parameter_in_block (pn_block, code, name, var_list) result (var)
      real(default) :: var
      type(parse_node_t), intent(in), target :: pn_block
      integer, intent(in) :: code
      type(string_t), intent(in) :: name
      type(var_list_t), intent(in), target :: var_list
      type(parse_node_t), pointer :: pn_data, pn_item
      call slha_find_index_ptr (pn_block, pn_data, pn_item, code)
      if (associated (pn_item)) then
         var = get_real_parameter (pn_item)
      else
         var = var_list_get_rval (var_list, name)
      end if
   end function get_parameter_in_block
```

Extract a real data item with index i. If it does exist, set it in the variable list, using the given name. If the variable is not present in the variable list, ignore it.

⟨*SLHA: procedures*⟩+≡
```
   subroutine set_data_item (pn_block, code, name, var_list)
      type(parse_node_t), intent(in), target :: pn_block
      integer, intent(in) :: code
      type(string_t), intent(in) :: name
      type(var_list_t), intent(inout), target :: var_list
      type(parse_node_t), pointer :: pn_data, pn_item
      call slha_find_index_ptr (pn_block, pn_data, pn_item, code)
      if (associated (pn_item)) then
         call var_list_set_real &
              (var_list, name,  get_real_parameter (pn_item), &
               is_known=.true., ignore=.true.)
      end if
   end subroutine set_data_item
```

Extract a real matrix element with index `i,j`. If it does exists, set it in the variable list, using the given name. If the variable is not present in the variable list, ignore it.

⟨*SLHA: procedures*⟩+≡
```
subroutine set_matrix_element (pn_block, code1, code2, name, var_list)
  type(parse_node_t), intent(in), target :: pn_block
  integer, intent(in) :: code1, code2
  type(string_t), intent(in) :: name
  type(var_list_t), intent(inout), target :: var_list
  type(parse_node_t), pointer :: pn_data, pn_item
  call slha_find_index_pair_ptr (pn_block, pn_data, pn_item, code1, code2)
  if (associated (pn_item)) then
     call var_list_set_real &
          (var_list, name,  get_real_parameter (pn_item), &
           is_known=.true., ignore=.true.)
  end if
end subroutine set_matrix_element
```

Transfer data from variables to SLHA

Get a real/integer parameter with index `i` from the variable list and write it to the current output file. In the integer case, we account for the fact that the variable is type real. If it does not exist, do nothing.

⟨*SLHA: procedures*⟩+≡
```
subroutine write_integer_data_item (u, code, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  integer :: item
  if (var_list_exists (var_list, name)) then
     item = nint (var_list_get_rval (var_list, name))
     call write_integer_parameter (u, code, item, comment)
  end if
end subroutine write_integer_data_item

subroutine write_real_data_item (u, code, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  real(default) :: item
  if (var_list_exists (var_list, name)) then
     item = var_list_get_rval (var_list, name)
     call write_real_parameter (u, code, item, comment)
  end if
end subroutine write_real_data_item
```

Get a real data item with two integer indices from the variable list and write it to the current output file. If it does not exist, do nothing.

⟨*SLHA: procedures*⟩+≡
```
subroutine write_matrix_element (u, code1, code2, name, var_list, comment)
  integer, intent(in) :: u
  integer, intent(in) :: code1, code2
  type(string_t), intent(in) :: name
  type(var_list_t), intent(in) :: var_list
  character(*), intent(in) :: comment
  real(default) :: item
  if (var_list_exists (var_list, name)) then
     item = var_list_get_rval (var_list, name)
     call write_real_matrix_element (u, code1, code2, item, comment)
  end if
end subroutine write_matrix_element
```

20.0.8 Auxiliary function

Write a block header.

⟨*SLHA: procedures*⟩+≡
```
subroutine write_block_header (u, name, comment)
  integer, intent(in) :: u
  character(*), intent(in) :: name, comment
  write (u, "(A,1x,A,3x,'#',1x,A)")  "BLOCK", name, comment
end subroutine write_block_header
```

Extract a real parameter that may be defined real or integer, signed or unsigned.

⟨*SLHA: procedures*⟩+≡
```
function get_real_parameter (pn_item) result (var)
  real(default) :: var
  type(parse_node_t), intent(in), target :: pn_item
  type(parse_node_t), pointer :: pn_sign, pn_var
  integer :: sign
  select case (char (parse_node_get_rule_key (pn_item)))
  case ("signed_number")
     pn_sign => parse_node_get_sub_ptr (pn_item)
     pn_var  => parse_node_get_next_ptr (pn_sign)
     select case (char (parse_node_get_key (pn_sign)))
     case ("+");  sign = +1
     case ("-");  sign = -1
     end select
  case default
     sign = +1
     pn_var => pn_item
  end select
  select case (char (parse_node_get_rule_key (pn_var)))
  case ("integer");  var = sign * parse_node_get_integer (pn_var)
  case ("real");     var = sign * parse_node_get_real (pn_var)
  end select
end function get_real_parameter
```

2725

Auxiliary: Extract an integer parameter that may be defined signed or unsigned.
A real value is an error.

⟨*SLHA: procedures*⟩+≡

```
    function get_integer_parameter (pn_item) result (var)
      integer :: var
      type(parse_node_t), intent(in), target :: pn_item
      type(parse_node_t), pointer :: pn_sign, pn_var
      integer :: sign
      select case (char (parse_node_get_rule_key (pn_item)))
      case ("signed_integer")
         pn_sign => parse_node_get_sub_ptr (pn_item)
         pn_var  => parse_node_get_next_ptr (pn_sign)
         select case (char (parse_node_get_key (pn_sign)))
         case ("+");  sign = +1
         case ("-");  sign = -1
         end select
      case ("integer")
         sign = +1
         pn_var => pn_item
      case default
         call parse_node_write (pn_var)
         call msg_error ("SLHA: Integer parameter expected")
         var = 0
         return
      end select
      var = sign * parse_node_get_integer (pn_var)
    end function get_integer_parameter
```

Write an integer parameter with a single index directly to file, using the required
output format.

⟨*SLHA: procedures*⟩+≡

```
    subroutine write_integer_parameter (u, code, item, comment)
      integer, intent(in) :: u
      integer, intent(in) :: code
      integer, intent(in) :: item
      character(*), intent(in) :: comment
  1   format (1x, I9, 3x, 3x, I9, 4x, 3x, '#', 1x, A)
      write (u, 1)  code, item, comment
    end subroutine write_integer_parameter
```

Write a real parameter with two indices directly to file, using the required output
format.

⟨*SLHA: procedures*⟩+≡

```
    subroutine write_real_parameter (u, code, item, comment)
      integer, intent(in) :: u
      integer, intent(in) :: code
      real(default), intent(in) :: item
      character(*), intent(in) :: comment
  1   format (1x, I9, 3x, 1P, E16.8, 0P, 3x, '#', 1x, A)
      write (u, 1)  code, item, comment
    end subroutine write_real_parameter
```

Write a real parameter with a single index directly to file, using the required output format.

⟨*SLHA: procedures*⟩+≡
```
    subroutine write_real_matrix_element (u, code1, code2, item, comment)
      integer, intent(in) :: u
      integer, intent(in) :: code1, code2
      real(default), intent(in) :: item
      character(*), intent(in) :: comment
  1   format (1x, I2, 1x, I2, 3x, 1P, E16.8, 0P, 3x, '#', 1x, A)
      write (u, 1)  code1, code2, item, comment
    end subroutine write_real_matrix_element
```

The concrete SLHA interpreter

SLHA codes for particular physics models

⟨*SLHA: parameters*⟩+≡
```
    integer, parameter :: MDL_MSSM = 0
    integer, parameter :: MDL_NMSSM = 1
```

Take the parse tree and extract relevant data. Select the correct model and store all data that is present in the appropriate variable list. Finally, update the variable record.

⟨*SLHA: procedures*⟩+≡
```
    subroutine slha_interpret_parse_tree &

    end subroutine slha_write_MODSEL
```

SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is
not defined in the block, we use the previous value from the model variable list.
For the basic parameters we have to do a small recalculation, since SLHA uses
the G_F-α-m_Z scheme, while WHIZARD derives them from G_F, m_W, and m_Z.

⟨*SLHA: procedures*⟩+≡
```
    subroutine slha_handle_SMINPUTS (parse_tree, model)
      type(parse_tree_t), intent(in) :: parse_tree
      type(model_t), intent(inout), target :: model
      type(parse_node_t), pointer :: pn_block
      real(default) :: alpha_em_i, GF, alphas, mZ
      real(default) :: ee, vv, cw_sw, cw2, mW
      real(default) :: mb, mtop, mtau
      type(var_list_t), pointer :: var_list
      var_list => model_get_var_list_ptr (model)

        call model_set_particle_width (model, pdg, width)
        pn_decay => slha_get_next_decay_ptr (pn_decay)
     end do
   end subroutine slha_handle_decays
```

Mixing matrices

Read mixing matrices. We can treat all matrices by a single procedure if we
just know the block name, variable prefix, and matrix dimension. The matrix
dimension must be less than 10. For the pseudoscalar Higgses in NMSSM-type
models we need off-diagonal matrices, so we generalize the definition.

⟨*SLHA: procedures*⟩+≡
```
   subroutine slha_handle_matrix_block &
        (parse_tree, block_name, var_prefix, dim1, dim2, model)
     type(parse_tree_t), intent(in) :: parse_tree
     character(*), intent(in) :: block_name, var_prefix
     integer, intent(in) :: dim1, dim2
     type(model_t), intent(inout), target :: model
     type(parse_node_t), pointer :: pn_block
     type(var_list_t), pointer :: var_list
     integer :: i, j
```

```
      character(len=len(var_prefix)+2) :: var_name
      var_list => model_get_var_list_ptr (model)
      pn_block => slha_get_block_ptr &
           (parse_tree, var_str (block_name), required=.false.)
      if (.not. (associated (pn_block)))  return
      do i = 1, dim1
         do j = 1, dim2
            write (var_name, "(A,I1,I1)")  var_prefix, i, j
            call set_matrix_element (pn_block, i, j, var_str (var_name), var_list)
         end do
      end do
    end subroutine slha_handle_matrix_block
```

Higgs data

Read the block ALPHA which holds just the Higgs mixing angle.

⟨*SLHA: procedures*⟩+≡

```
    subroutine slha_handle_ALPHA (parse_tree, model)
      type(parse_tree_t), intent(in) :: parse_tree
      type(model_t), intent(inout), target :: model
      type(parse_node_t), pointer :: pn_block, pn_line, pn_data, pn_item
      type(var_list_t), pointer :: var_list
      real(default) :: al_h
      var_list => model_get_var_list_ptr (model)
      pn_block => slha_get_block_ptr &
           (parse_tree, var_str ("ALPHA"), required=.false.)
      if (.not. (associated (pn_block)))  return
      pn_data => parse_node_get_sub_ptr (pn_block, 4)
      pn_line => parse_node_get_sub_ptr (pn_data, 2)
      pn_item => parse_node_get_sub_ptr (pn_line)
      if (associated (pn_item)) then
         al_h = get_real_parameter (pn_item)
         call var_list_set_real (var_list, var_str ("al_h"), al_h, &
              is_known=.true., ignore=.true.)
      end if
    end subroutine slha_handle_ALPHA
```

Read the block HMIX for the Higgs mixing parameters

⟨*SLHA: procedures*⟩+≡

```
    subroutine slha_handle_HMIX (parse_tree, model)
      type(parse_tree_t), intent(in) :: parse_tree
      type(model_t), intent(inout), target :: model
      type(parse_node_t), pointer :: pn_block
      type(var_list_t), pointer :: var_list
      var_list => model_get_var_list_ptr (model)
      pn_block => slha_get_block_ptr &
           (parse_tree, var_str ("HMIX"), required=.false.)
      if (.not. (associated (pn_block)))  return
      call set_data_item (pn_block, 1, var_str ("mu_h"), var_list)
      call set_data_item (pn_block, 2, var_str ("tanb_h"), var_list)
    end subroutine slha_handle_HMIX
```

Read the block NMSSMRUN for the specific NMSSM parameters

⟨SLHA: procedures⟩+≡
```
subroutine slha_handle_NMSSMRUN (parse_tree, model)
  type(parse_tree_t), intent(in) :: parse_tree
  type(model_t), intent(inout), target :: model
  type(parse_node_t), pointer :: pn_block
  type(var_list_t), pointer :: var_list
  var_list => model_get_var_list_ptr (model)
  pn_block => slha_get_block_ptr &
       (parse_tree, var_str ("NMSSMRUN"), required=.false.)
  if (.not. (associated (pn_block)))  return
  call set_data_item (pn_block, 1, var_str ("ls"), var_list)
  call set_data_item (pn_block, 2, var_str ("ks"), var_list)
  call set_data_item (pn_block, 3, var_str ("a_ls"), var_list)
  call set_data_item (pn_block, 4, var_str ("a_ks"), var_list)
  call set_data_item (pn_block, 5, var_str ("nmu"), var_list)
  end subroutine slha_handle_NMSSMRUN
```

20.0.9 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

⟨SLHA: procedures⟩+≡
```
subroutine slha_parse_stream (stream, parse_tree)
  type(stream_t), intent(inout), target :: stream
  type(parse_tree_t), intent(out) :: parse_tree
  type(ifile_t) :: ifile
  type(lexer_t) :: lexer
  type(stream_t), target :: stream_tmp
  call slha_preprocess (stream, ifile)
  call stream_init (stream_tmp, ifile)
  call lexer_init_slha (lexer)
  call lexer_assign_stream (lexer, stream_tmp)
  call parse_tree_init (parse_tree, syntax_slha, lexer)
  call lexer_final (lexer)
  call stream_final (stream_tmp)
  call ifile_final (ifile)
end subroutine slha_parse_stream
```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

⟨SLHA: procedures⟩+≡
```
subroutine slha_parse_file (file, os_data, parse_tree)
  type(string_t), intent(in) :: file
  type(os_data_t), intent(in) :: os_data
  type(parse_tree_t), intent(out) :: parse_tree
  logical :: exist
  type(string_t) :: filename
  type(stream_t), target :: stream
  call msg_message ("Reading SLHA input file '" // char (file) // "'")
  filename = file
```

```
      inquire (file=char(filename), exist=exist)
      if (.not. exist) then
         filename = os_data%whizard_susypath // "/" // file
         inquire (file=char(filename), exist=exist)
         if (.not. exist) then
            call msg_fatal ("SLHA input file '" // char (file) // "' not found")
            return
         end if
      end if
      call stream_init (stream, char (filename))
      call slha_parse_stream (stream, parse_tree)
      call stream_final (stream)
   end subroutine slha_parse_file
```

20.0.10   API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters
retrieved from the file will be inserted into the appropriate model, which is
loaded and modified in the background. The pointer to this model is returned
as the last argument.

⟨*SLHA: public*⟩+≡
```
   public :: slha_read_file
```

⟨*SLHA: procedures*⟩+≡
```
   subroutine slha_read_file &
        (file, os_data, model_list, model, input, spectrum, decays)

Chapter 21

NLO infrastructure

21.1 BLHA interface

These modules implement the communication with one loop matrix element providers according to the Binoth LesHouches Accord Interface. The actual matrix element(s) are loaded as a dynamic library.

The module is split into a configuration interface which manages configuration and handles the request and contract files, a module which interfaces the OLP matrix elements and a driver.

21.1.2 OLP matrix element interface

The prototypes of the OLP functions.

⟨*BLHA interface: interfaces*⟩≡

```
   abstract interface
      subroutine ext_olp_start (file, status) bind(c)
        import
        character(c_char), dimension(*), intent(in) :: file
        integer(c_int), intent(out) :: status
      end subroutine ext_olp_Start

      subroutine ext_olp_evalsubprocess &
           (label, momenta, scale, parameters, amp) bind(c)
        import
        integer(c_int), intent(in), value :: label
        real(c_double), dimension(*), intent(in) :: momenta
        real(c_double), intent(in), value :: scale
        real(c_double), dimension(*), intent(in) :: parameters
        real(c_double), dimension(*), intent(out) :: amp
      end subroutine ext_olp_evalsubprocess

      subroutine ext_olp_finalize () bind(c)
      end subroutine ext_olp_finalize

      subroutine ext_olp_option (assignment, status) bind(c)
        import
        character(c_char), dimension(*), intent(in) :: assignment
        integer(c_int), intent(out) :: status
      end subroutine ext_olp_option
   end interface
```

The OLP library is encapsulated together with the configuration in derived type:

⟨*BLHA interface: public*⟩≡
```
public :: blha_olp_t
```

⟨*BLHA interface: types*⟩≡
```
type :: blha_olp_t
   private
   type(blha_configuration_t) :: cfg
   type(string_t) :: library
   integer :: n_in, n_out, n_flv, n_hel, n_col
   integer, dimension(:,:), allocatable :: flv_state
   logical :: color_summed = .true., flavor_summed = .true.
   logical :: loaded = .false.
   type(dlaccess_t) :: lib_handle
   procedure(ext_olp_start), pointer, nopass :: olp_start => null ()
   procedure(ext_olp_evalsubprocess), pointer, nopass :: &
      olp_evalsubprocess => null ()
   procedure(ext_olp_finalize), pointer, nopass :: olp_finalize => null ()
   procedure(ext_olp_option), pointer, nopass :: olp_option => null ()
end type blha_olp_t
```

Init the `blha_olp_t` object and try to dlopen the library.

            success = .false.
         else
            call msg_fatal (msg)
         end if
       end subroutine error

    end subroutine blha_olp_init
```

Finalizer.

⟨*BLHA interface: public*⟩+≡
```
    public :: blha_olp_final
```

⟨*BLHA interface: procedures*⟩+≡
```
    subroutine blha_olp_final (olp)
      type(blha_olp_t), intent(inout) :: olp
      if (.not. olp%loaded) return
      if (associated (olp%olp_finalize)) call olp%olp_finalize
      call dlaccess_final (olp%lib_handle)
      olp%loaded = .false.
    end subroutine blha_olp_final
```

Test.

⟨*BLHA interface: public*⟩+≡
```
    public :: blha_interface_test
```

⟨*BLHA interface: procedures*⟩+≡
```
    subroutine blha_interface_test (cfg, ok)
      type(blha_configuration_t), intent(inout) :: cfg
      type(blha_olp_t) :: olp
      logical, intent(out) :: ok
      call blha_olp_init (olp, cfg, library=var_str ("blha_test.so"), success=ok)
      print *, "loading OLP library: success?", ok
      call blha_olp_final (olp)
    end subroutine blha_interface_test
```

21.1.3 OLP driver

⟨*BLHA driver: public*⟩≡
```
    public :: blha_test
```

⟨*BLHA driver: procedures*⟩≡
```
    subroutine blha_test (model)
      type(model_t), pointer :: model
      type (blha_configuration_t) :: cfg
      logical :: ok
      call blha_config_test (model, cfg, ok)
      if (ok) call blha_interface_test (cfg, ok)
    end subroutine blha_test
```

Chapter 22

Integration and simulation

This layer of modules is just below the top-level API. We lay out specific data types for integration and simulation and implement the corresponding algorithms as methods acting on them. This helps to keep the command-level implementation concise and simple.

22.1 Iterations

This module defines a container for the list of iterations and calls, to be submitted to integration.

⟨`iterations.f90`⟩≡
  ⟨*File header*⟩

  ```
  module iterations
  ```

  ⟨*Use strings*⟩
  ⟨*Use file utils*⟩
  ```
    use diagnostics !NODEP!
    use unit_tests
    use processes
  ```

  ⟨*Standard module head*⟩

  ⟨*Iterations: public*⟩

  ⟨*Iterations: types*⟩

  ```
  contains
  ```

  ⟨*Iterations: procedures*⟩

  ⟨*Iterations: tests*⟩

  ```
  end module iterations
  ```

22.1.1 The iterations list

Each integration pass has a number of iterations and a number of calls per iteration. The last pass produces the end result; the previous passes are used for adaptation.

The flags `adapt_grid` and `adapt_weight` are used only if `custom_adaptation` is set. Otherwise, default settings are used that depend on the integration pass.

⟨*Iterations: types*⟩≡
```
type :: iterations_spec_t
  private
  integer :: n_it = 0
  integer :: n_calls = 0
  logical :: custom_adaptation = .false.
  logical :: adapt_grids = .false.
  logical :: adapt_weights = .false.
end type iterations_spec_t
```

We build up a list of iterations.

⟨*Iterations: public*⟩≡
```
public :: iterations_list_t
```

⟨*Iterations: types*⟩+≡
```
type :: iterations_list_t
  private
  integer :: n_pass = 0
  type(iterations_spec_t), dimension(:), allocatable :: pass
 contains
 ⟨Iterations: iterations list: TBP⟩
end type iterations_list_t
```

Initialize an iterations list. For each pass, we have to specify the number of iterations and calls. We may provide the adaption conventions explicitly, either as character codes or as logicals.

For passes where the adaptation conventions are not specified, we use the following default setting: adapt weights and grids for all passes except the last one.

⟨*Iterations: iterations list: TBP*⟩≡
```
procedure :: init => iterations_list_init
```

⟨*Iterations: procedures*⟩≡
```
subroutine iterations_list_init &
    (it_list, n_it, n_calls, adapt, adapt_code, adapt_grids, adapt_weights)
  class(iterations_list_t), intent(inout) :: it_list
  integer, dimension(:), intent(in) :: n_it, n_calls
  logical, dimension(:), intent(in), optional :: adapt
  type(string_t), dimension(:), intent(in), optional :: adapt_code
  logical, dimension(:), intent(in), optional :: adapt_grids, adapt_weights
  integer :: i
  it_list%n_pass = size (n_it)
  if (allocated (it_list%pass)) deallocate (it_list%pass)
  allocate (it_list%pass (it_list%n_pass))
  it_list%pass%n_it = n_it
  it_list%pass%n_calls = n_calls
```

```
        if (present (adapt)) then
           it_list%pass%custom_adaptation = adapt
           do i = 1, it_list%n_pass
              if (adapt(i)) then
                 if (verify (adapt_code(i), "wg") /= 0) then
                    call msg_error ("iteration specification: " &
                         // "adaptation code letters must be 'w' or 'g'")
                 end if
                 it_list%pass(i)%adapt_grids = scan (adapt_code(i), "g") /= 0
                 it_list%pass(i)%adapt_weights = scan (adapt_code(i), "w") /= 0
              end if
           end do
        else if (present (adapt_grids) .and. present (adapt_weights)) then
           it_list%pass%custom_adaptation = .true.
           it_list%pass%adapt_grids = adapt_grids
           it_list%pass%adapt_weights = adapt_weights
        end if
        do i = 1, it_list%n_pass - 1
           if (.not. it_list%pass(i)%custom_adaptation) then
              it_list%pass(i)%adapt_grids = .true.
              it_list%pass(i)%adapt_weights = .true.
           end if
        end do
     end subroutine iterations_list_init
```

⟨*Iterations: iterations list: TBP*⟩+≡
```
     procedure :: clear => iterations_list_clear
```

⟨*Iterations: procedures*⟩+≡
```
     subroutine iterations_list_clear (it_list)
       class(iterations_list_t), intent(inout) :: it_list
       it_list%n_pass = 0
       deallocate (it_list%pass)
     end subroutine iterations_list_clear
```

Write the list of iterations.

⟨*Iterations: iterations list: TBP*⟩+≡
```
     procedure :: write => iterations_list_write
```

⟨*Iterations: procedures*⟩+≡
```
     subroutine iterations_list_write (it_list, unit)
       class(iterations_list_t), intent(in) :: it_list
       integer, intent(in), optional :: unit
       integer :: u
       u = output_unit (unit)
       write (u, "(A)")  char (it_list%to_string ())
     end subroutine iterations_list_write
```

The output as a single-line string.

⟨*Iterations: iterations list: TBP*⟩+≡
```
     procedure :: to_string => iterations_list_to_string
```

⟨*Iterations: procedures*⟩+≡
```
     function iterations_list_to_string (it_list) result (buffer)
```

```
      class(iterations_list_t), intent(in) :: it_list
      type(string_t) :: buffer
      character(30) :: ibuf
      integer :: i
      buffer = "iterations = "
      if (it_list%n_pass > 0) then
         do i = 1, it_list%n_pass
            if (i > 1)  buffer = buffer // ", "
            write (ibuf, "(I0,':',I0)") &
                 it_list%pass(i)%n_it, it_list%pass(i)%n_calls
            buffer = buffer // trim (ibuf)
            if (it_list%pass(i)%custom_adaptation &
                 .or. it_list%pass(i)%adapt_grids &
                 .or. it_list%pass(i)%adapt_weights) then
               buffer = buffer // ':"'
               if (it_list%pass(i)%adapt_grids)  buffer = buffer // "g"
               if (it_list%pass(i)%adapt_weights)  buffer = buffer // "w"
               buffer = buffer // '"'
            end if
         end do
      else
         buffer = buffer // "[undefined]"
      end if
   end function iterations_list_to_string
```

22.1.2 Tools

Return the total number of passes.

⟨*Iterations: iterations list: TBP*⟩+≡
```
   procedure :: get_n_pass => iterations_list_get_n_pass
```

⟨*Iterations: procedures*⟩+≡
```
   function iterations_list_get_n_pass (it_list) result (n_pass)
     class(iterations_list_t), intent(in) :: it_list
     integer :: n_pass
     n_pass = it_list%n_pass
   end function iterations_list_get_n_pass
```

Return the number of calls for a specific pass.

⟨*Iterations: iterations list: TBP*⟩+≡
```
   procedure :: get_n_calls => iterations_list_get_n_calls
```

⟨*Iterations: procedures*⟩+≡
```
   function iterations_list_get_n_calls (it_list, pass) result (n_calls)
     class(iterations_list_t), intent(in) :: it_list
     integer :: n_calls
     integer, intent(in) :: pass
     if (pass <= it_list%n_pass) then
        n_calls = it_list%pass(pass)%n_calls
     else
        n_calls = 0
     end if
   end function iterations_list_get_n_calls
```

Get the adaptation mode (automatic/custom) and, for custom adaptation, the flags for a specific pass.

⟨*Iterations: iterations list: TBP*⟩+≡
```
    procedure :: adapt_grids => iterations_list_adapt_grids
    procedure :: adapt_weights => iterations_list_adapt_weights
```

⟨*Iterations: procedures*⟩+≡
```
    function iterations_list_adapt_grids (it_list, pass) result (flag)
      logical :: flag
      class(iterations_list_t), intent(in) :: it_list
      integer, intent(in) :: pass
      if (pass <= it_list%n_pass) then
         flag = it_list%pass(pass)%adapt_grids
      else
         flag = .false.
      end if
    end function iterations_list_adapt_grids

    function iterations_list_adapt_weights (it_list, pass) result (flag)
      logical :: flag
      class(iterations_list_t), intent(in) :: it_list
      integer, intent(in) :: pass
      if (pass <= it_list%n_pass) then
         flag = it_list%pass(pass)%adapt_weights
      else
         flag = .false.
      end if
    end function iterations_list_adapt_weights
```

Return the total number of iterations / the iterations for a specific pass.

⟨*Iterations: iterations list: TBP*⟩+≡
```
    procedure :: get_n_it => iterations_list_get_n_it
```

⟨*Iterations: procedures*⟩+≡
```
    function iterations_list_get_n_it (it_list, pass) result (n_it)
      class(iterations_list_t), intent(in) :: it_list
      integer :: n_it
      integer, intent(in) :: pass
      if (pass <= it_list%n_pass) then
         n_it = it_list%pass(pass)%n_it
      else
         n_it = 0
      end if
    end function iterations_list_get_n_it
```

22.1.3 Test

This is the master for calling self-test procedures.

⟨*Iterations: public*⟩+≡
```
    public :: iterations_test
```

⟨*Iterations: tests*⟩≡
```
    subroutine iterations_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
    ⟨Iterations: execute tests⟩
  end subroutine iterations_test
```

Empty list

⟨*Iterations: execute tests*⟩≡
```
    call test (iterations_1, "iterations_1", &
        "empty iterations list", &
        u, results)
```
⟨*Iterations: tests*⟩+≡
```
    subroutine iterations_1 (u)
      integer, intent(in) :: u
      type(iterations_list_t) :: it_list

      write (u, "(A)")  "* Test output: iterations_1"
      write (u, "(A)")  "*   Purpose: display empty iterations list"
      write (u, "(A)")

      call it_list%write (u)

      write (u, "(A)")
      write (u, "(A)")  "* Test output end: iterations_1"

    end subroutine iterations_1
```

Fill list

⟨*Iterations: execute tests*⟩+≡
```
    call test (iterations_2, "iterations_2", &
        "create iterations list", &
        u, results)
```
⟨*Iterations: tests*⟩+≡
```
    subroutine iterations_2 (u)
      integer, intent(in) :: u
      type(iterations_list_t) :: it_list

      write (u, "(A)")  "* Test output: iterations_2"
      write (u, "(A)")  "*   Purpose: fill and display iterations list"
      write (u, "(A)")

      write (u, "(A)")  "* Minimal setup (2 passes)"
      write (u, "(A)")

      call it_list%init ([2, 4], [5000, 20000])

      call it_list%write (u)
      call it_list%clear ()
```

2772

```
      write (u, "(A)")
      write (u, "(A)")   "* Setup with flags (3 passes)"
      write (u, "(A)")

      call it_list%init ([2, 4, 5], [5000, 20000, 400], &
           [.false., .true., .true.], &
           [var_str (""), var_str ("g"), var_str ("wg")])

      call it_list%write (u)

      write (u, "(A)")
      write (u, "(A)")   "* Extract data"
      write (u, "(A)")

      write (u, "(A,I0)")   "n_pass = ", it_list%get_n_pass ()
      write (u, "(A)")
      write (u, "(A,I0)")   "n_calls(2) = ", it_list%get_n_calls (2)
      write (u, "(A)")
      write (u, "(A,I0)")   "n_it(3) = ", it_list%get_n_it (3)

      write (u, "(A)")
      write (u, "(A)")   "* Test output end: iterations_2"

    end subroutine iterations_2
```

22.2   User-controlled File I/O

The SINDARIN language includes commands that write output to file (input
may be added later). We identify files by their name, and manage the unit
internally. We need procedures for opening, closing, and printing files.

⟨user_files.f90⟩≡
  ⟨*File header*⟩

```
  module user_files
```

  ⟨*Use strings*⟩
  ⟨*Use file utils*⟩
```
    use diagnostics !NODEP!
    use ifiles
    use analysis
```

  ⟨*Standard module head*⟩

  ⟨*User files: public*⟩

  ⟨*User files: types*⟩

  ⟨*User files: interfaces*⟩

```
  contains
```

2773

⟨*User files: procedures*⟩

```
  end module user_files
```

22.2.1 The file type

This is a type that describes an open user file and its properties. The entry is part of a doubly-linked list.

⟨*User files: types*⟩≡
```
    type :: file_t
       private
       type(string_t) :: name
       integer :: unit = -1
       logical :: reading = .false.
       logical :: writing = .false.
       type(file_t), pointer :: prev => null ()
       type(file_t), pointer :: next => null ()
    end type file_t
```

The initializer opens the file.

⟨*User files: procedures*⟩≡
```
    subroutine file_init (file, name, action, status, position)
      type(file_t), intent(out) :: file
      type(string_t), intent(in) :: name
      character(len=*), intent(in) :: action, status, position
      file%unit = free_unit ()
      file%name = name
      open (unit = file%unit, file = char (file%name), &
            action = action, status = status, position = position)
      select case (action)
      case ("read")
         file%reading = .true.
      case ("write")
         file%writing = .true.
      case ("readwrite")
         file%reading = .true.
         file%writing = .true.
      end select
    end subroutine file_init
```

The finalizer closes it.

⟨*User files: procedures*⟩+≡
```
    subroutine file_final (file)
      type(file_t), intent(inout) :: file
      close (unit = file%unit)
      file%unit = -1
    end subroutine file_final
```

Check if a file is open with correct status.

⟨*User files: procedures*⟩+≡

```
function file_is_open (file, action) result (flag)
  logical :: flag
  type(file_t), intent(in) :: file
  character(*), intent(in) :: action
  select case (action)
  case ("read")
     flag = file%reading
  case ("write")
     flag = file%writing
  case ("readwrite")
     flag = file%reading .and. file%writing
  case default
     call msg_bug ("Checking file '" // char (file%name) &
           // "': illegal action specifier")
  end select
end function file_is_open
```

Write to the file. Error if in wrong mode. If there is no string, just write an empty record. If there is a string, respect the `advancing` option.

⟨*User files: procedures*⟩+≡
```
subroutine file_write_string (file, string, advancing)
  type(file_t), intent(in) :: file
  type(string_t), intent(in), optional :: string
  logical, intent(in), optional :: advancing
  if (file%writing) then
     if (present (string)) then
        if (present (advancing)) then
           if (advancing) then
              write (file%unit, "(A)")  char (string)
           else
              write (file%unit, "(A)", advance="no")  char (string)
           end if
        else
           write (file%unit, "(A)")  char (string)
        end if
     else
        write (file%unit, *)
     end if
  else
     call msg_error ("Writing to file: File '" // char (file%name) &
           // "' is not open for writing.")
  end if
end subroutine file_write_string
```

Write a whole ifile, line by line.

⟨*User files: procedures*⟩+≡
```
subroutine file_write_ifile (file, ifile)
  type(file_t), intent(in) :: file
  type(ifile_t), intent(in) :: ifile
  type(line_p) :: line
  call line_init (line, ifile)
  do while (line_is_associated (line))
     call file_write_string (file, line_get_string_advance (line))
```

```
        end do
    end subroutine file_write_ifile
```

Write an analysis object (or all objects) to an open file.

⟨*User files: procedures*⟩+≡
```
    subroutine file_write_analysis (file, tag)
      type(file_t), intent(in) :: file
      type(string_t), intent(in), optional :: tag
      if (file%writing) then
         if (present (tag)) then
            call analysis_write (tag, unit = file%unit)
         else
            call analysis_write (unit = file%unit)
         end if
      else
         call msg_error ("Writing analysis to file: File '" // char (file%name) &
              // "' is not open for writing.")
      end if
    end subroutine file_write_analysis
```

22.2.2 The file list

We maintain a list of all open files and their attributes. The list must be doubly-linked because we may delete entries.

⟨*User files: public*⟩≡
```
    public :: file_list_t
```

⟨*User files: types*⟩+≡
```
    type :: file_list_t
      type(file_t), pointer :: first => null ()
      type(file_t), pointer :: last => null ()
    end type file_list_t
```

There is no initialization routine, but a finalizer which deletes all:

⟨*User files: public*⟩+≡
```
    public :: file_list_final
```

⟨*User files: procedures*⟩+≡
```
    subroutine file_list_final (file_list)
      type(file_list_t), intent(inout) :: file_list
      type(file_t), pointer :: current
      do while (associated (file_list%first))
         current => file_list%first
         file_list%first => current%next
         call file_final (current)
         deallocate (current)
      end do
      file_list%last => null ()
    end subroutine file_list_final
```

Find an entry in the list. Return null pointer on failure.

⟨*User files: procedures*⟩+≡
```
function file_list_get_file_ptr (file_list, name) result (current)
  type(file_t), pointer :: current
  type(file_list_t), intent(in) :: file_list
  type(string_t), intent(in) :: name
  current => file_list%first
  do while (associated (current))
     if (current%name == name)  return
     current => current%next
  end do
end function file_list_get_file_ptr
```

Check if a file is open, public version:

⟨*User files: public*⟩+≡
```
public :: file_list_is_open
```

⟨*User files: procedures*⟩+≡
```
function file_list_is_open (file_list, name, action) result (flag)
  logical :: flag
  type(file_list_t), intent(in) :: file_list
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action
  type(file_t), pointer :: current
  current => file_list_get_file_ptr (file_list, name)
  if (associated (current)) then
     flag = file_is_open (current, action)
  else
     flag = .false.
  end if
end function file_list_is_open
```

Append a new file entry, i.e., open this file. Error if it is already open.

⟨*User files: public*⟩+≡
```
public :: file_list_open
```

⟨*User files: procedures*⟩+≡
```
subroutine file_list_open (file_list, name, action, status, position)
  type(file_list_t), intent(inout) :: file_list
  type(string_t), intent(in) :: name
  character(len=*), intent(in) :: action, status, position

22.3.1 Container for parse nodes

The runtime data set contains a bunch of parse nodes (chunks of code that have
not been compiled into evaluation trees but saved for later use). We collect
them here.

This implementation has the useful effect that an assignment between two objects of this type will establish a pointer-target relationship for all components.

⟨*RT data: types*⟩≡
```
type :: rt_parse_nodes_t
   type(parse_node_t), pointer :: cuts_lexpr => null ()
   type(parse_node_t), pointer :: scale_expr => null ()
   type(parse_node_t), pointer :: fac_scale_expr => null ()
   type(parse_node_t), pointer :: ren_scale_expr => null ()
   type(parse_node_t), pointer :: weight_expr => null ()
   type(parse_node_t), pointer :: selection_lexpr => null ()
   type(parse_node_t), pointer :: reweight_expr => null ()
   type(parse_node_t), pointer :: analysis_lexpr => null ()
   type(parse_node_p), dimension(:), allocatable :: alt_setup
 contains
 ⟨RT data: rt parse nodes: TBP⟩
 end type rt_parse_nodes_t
```

Clear individual components. The parse nodes are nullified. No finalization needed since the pointer targets are part of the global parse tree.

⟨*RT data: rt parse nodes: TBP*⟩≡
```
procedure :: clear => rt_parse_nodes_clear
```

⟨*RT data: procedures*⟩≡
```
subroutine rt_parse_nodes_clear (rt_pn, name)
  class(rt_parse_nodes_t), intent(inout) :: rt_pn
  type(string_t), intent(in) :: name
  select case (char (name))
  case ("cuts")
     rt_pn%cuts_lexpr => null ()
  case ("scale")
     rt_pn%scale_expr => null ()
  case ("factorization_scale")
     rt_pn%fac_scale_expr => null ()
  case ("renormalization_scale")
     rt_pn%ren_scale_expr => null ()
  case ("weight")

22.3.2 Container for particle data

If we locally modify particle properties, we must be able to revert them to their
original status. This transparent container stores the original state for a stack
of particles.

⟨*RT data: types*⟩+≡
```
    type :: rt_particle_entry_t
       integer :: pdg = 0
       logical :: stable = .true.
       logical :: isotropic = .false.
       logical :: diagonal = .false.
       logical :: polarized = .false.
       type(rt_particle_entry_t), pointer :: next => null ()
    end type rt_particle_entry_t
```

⟨*RT data: types*⟩+≡
```
    type :: rt_particle_stack_t
       type(model_t), pointer :: model => null ()
       type(rt_particle_entry_t), pointer :: first => null ()
     contains
     ⟨RT data: rt particle stack: TBP⟩
    end type rt_particle_stack_t
```

Finalize the stack.

⟨*RT data: rt particle stack: TBP*⟩≡

```
      procedure :: final => rt_particle_stack_final
⟨RT data: procedures⟩+≡
    subroutine rt_particle_stack_final (object)
      class(rt_particle_stack_t), intent(inout) :: object
      type(rt_particle_entry_t), pointer :: entry
      do while (associated (object%first))
         entry => object%first
         object%first => entry%next
         deallocate (entry)
      end do
      object%model => null ()
    end subroutine rt_particle_stack_final
```

Write the current contents of the particle stack, if it is nonempty.
⟨*RT data: rt particle stack: TBP*⟩+≡
```
      procedure :: write => rt_particle_stack_write
```
⟨*RT data: procedures*⟩+≡
```
    subroutine rt_particle_stack_write (object, unit)
      class(rt_particle_stack_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u
      type(rt_particle_entry_t), pointer :: entry
      u = output_unit (unit)
      if (.not. object%is_empty ()) then
         write (u, "(1x,A)")  "Stored particle data"
         if (associated (object%model)) then
            write (u, "(3x,A,A)") "Model = ", char (object%model%get_name ())
         else
            write (u, "(3x,A,A)") "Model = [undefined]"
         end if
         entry => object%first
         do while (associated (entry))
            write (u, "(3x,I0,':',4(2x,A,L1))")  entry%pdg, &
                 "stable = ", entry%stable, &
                 "isotropic = ", entry%isotropic, &
                 "diagonal = ", entry%diagonal, &
                 "polarized = ", entry%polarized
            entry => entry%next
         end do
      end if
    end subroutine rt_particle_stack_write
```

Initialize for a model.
⟨*RT data: rt particle stack: TBP*⟩+≡
```
      procedure :: init => rt_particle_stack_init
```
⟨*RT data: procedures*⟩+≡
```
    subroutine rt_particle_stack_init (stack, model)
      class(rt_particle_stack_t), intent(out) :: stack
      type(model_t), intent(in), target :: model
      stack%model => model
    end subroutine rt_particle_stack_init
```

Reset a stack: if the model changes, discard the previous stack and re-initialize.

⟨*RT data: rt particle stack: TBP*⟩+≡
```
procedure :: reset => rt_particle_stack_reset
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_particle_stack_reset (stack, model)
  class(rt_particle_stack_t), intent(inout) :: stack
  type(model_t), intent(in), target :: model
  if (associated (stack%model)) then
     if (model%get_name () /= stack%model%get_name ()) then
        call stack%final ()
        call stack%init (model)
     end if
  else
     call stack%init (model)
  end if
end subroutine rt_particle_stack_reset
```

Push an entry on the stack, storing the current state of the particle in the model.

⟨*RT data: rt particle stack: TBP*⟩+≡
```
procedure :: push => rt_particle_stack_push
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_particle_stack_push (stack, pdg)
  class(rt_particle_stack_t), intent(inout) :: stack
  integer, intent(in) :: pdg
  type(rt_particle_entry_t), pointer :: entry
  type(particle_data_t), pointer :: prt_data
  logical :: anti
  allocate (entry)
  entry%pdg = pdg
  anti = pdg < 0
  prt_data => model_get_particle_ptr (stack%model, pdg)
  entry%stable = particle_data_is_stable (prt_data, anti)
  entry%polarized = particle_data_is_polarized (prt_data, anti)
  entry%isotropic = particle_data_decays_isotropically (prt_data, anti)
  entry%diagonal = particle_data_decays_diagonal (prt_data, anti)
  entry%next => stack%first
  stack%first => entry
end subroutine rt_particle_stack_push
```

⟨*RT data: rt particle stack: TBP*⟩+≡
```
procedure :: is_empty => rt_particle_stack_is_empty
```

⟨*RT data: procedures*⟩+≡
```
function rt_particle_stack_is_empty (stack) result (flag)
  class(rt_particle_stack_t), intent(in) :: stack
  logical :: flag
  flag = .not. associated (stack%first)
end function rt_particle_stack_is_empty
```

Check whether a particle is already on the stack.

⟨*RT data: rt particle stack: TBP*⟩+≡
```
procedure :: contains => rt_particle_stack_contains
```

⟨*RT data: procedures*⟩+≡
```
function rt_particle_stack_contains (stack, pdg) result (flag)
  class(rt_particle_stack_t), intent(in) :: stack
  integer, intent(in) :: pdg
  logical :: flag
  type(rt_particle_entry_t), pointer :: entry
  flag = .false.
  entry => stack%first
  do while (associated (entry))
     if (entry%pdg == pdg) then
        flag = .true.;  return
     end if
     entry => entry%next
  end do
end function rt_particle_stack_contains
```

Restore the previous state of the model that is referenced by the particle stack.
Then, we can delete the stack since it is no longer necessary.

⟨*RT data: rt particle stack: TBP*⟩+≡
```
procedure :: restore_model => rt_particle_stack_restore_model
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_particle_stack_restore_model (stack)

      call global%beam_structure%final_pol ()
      call global%beam_structure%final_mom ()
    end subroutine rt_data_clear_beams
```

22.3.6 Initialization

Initialize runtime data. This defines special variables such as `sqrts`, and should be done only for the instance that is actually global. Local copies will inherit the special variables.

   We link the global variable list to the process stack variable list, so the latter is always available (and kept global).

⟨RT data: rt data: TBP⟩+≡
```
    procedure :: global_init => rt_data_global_init
```

⟨RT data: procedures⟩+≡
```
    subroutine rt_data_global_init (global, paths, logfile)

      end subroutine rt_data_global_init
```

22.3.7   Local copies

This is done at compile time when a local copy of runtime data is needed:
Link the variable list and initialize all derived parameters. This allows for
synchronizing them with local variable changes without affecting global data.

Also re-initialize pointer variables, so they point to local copies of their
targets.

⟨*RT data: rt data: TBP*⟩+≡
```
    procedure :: local_init => rt_data_local_init
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_data_local_init (local, global, env)
  class(rt_data_t), intent(inout), target :: local
  class(rt_data_t), intent(in), target :: global
  integer, intent(in), optional :: env
  call var_list_link (local%var_list, global%var_list)
  if (associated (global%model)) then
     call var_list_init_copies (local%var_list, &
          model_get_var_list_ptr (global%model), &
          derived_only = .true.)
  end if
  call local%init_pointer_variables ()
  local%os_data = global%os_data
  local%logfile = global%logfile
end subroutine rt_data_local_init
```

This copies global objects, for which local modifications should be kept.

⟨*RT data: rt data: TBP*⟩+≡
```
procedure :: copy_globals => rt_data_copy_globals
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_data_copy_globals (global, local)
  class(rt_data_t), intent(in) :: global
  class(rt_data_t), intent(inout) :: local
  local%model_list = global%model_list
  local%prclib_stack = global%prclib_stack
  local%process_stack = global%process_stack
end subroutine rt_data_copy_globals
```

These variables point to objects which get local copies:

⟨*RT data: rt data: TBP*⟩+≡
```
procedure :: init_pointer_variables => rt_data_init_pointer_variables
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_data_init_pointer_variables (local)
  class(rt_data_t), intent(inout), target :: local
  logical, target, save :: known = .true.
  call var_list_append_string_ptr &
       (local%var_list, var_str ("$fc"), local%os_data%fc, known, &
        intrinsic=.true.)
  call var_list_append_string_ptr &
       (local%var_list, var_str ("$fcflags"), local%os_data%fcflags, known, &
        intrinsic=.true.)
end subroutine rt_data_init_pointer_variables
```

This is done at execution time: Copy data, transfer pointers. `local` has intent(inout) because its local variable list has already been prepared by the previous routine.

To be pedantic, the local pointers to model and library should point to the entries in the local copies. (However, as long as these are just shallow copies with identical content, this is actually irrelevant.)

The process library and process stacks behave as global objects. The copies of the process library and process stacks should be shallow copies, so the contents stay identical. Since objects may be pushed on the stack in the local environment, upon restoring the global environment, we should reverse the assignment. Then the added stack elements will end up on the global stack. (This should be reconsidered in a parallel environment.)

⟨*RT data: rt data: TBP*⟩+≡
```
procedure :: link => rt_data_link
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_data_link (local, global)
  class(rt_data_t), intent(inout), target :: local
  class(rt_data_t), intent(in), target :: global
  local%lexer => global%lexer
  call global%copy_globals (local)
  local%os_data = global%os_data
  local%logfile = global%logfile
  call var_list_link (local%var_list, global%var_list)
  if (associated (global%model)) then
     local%model => &
          local%model_list%get_model_ptr (global%model%get_name ())
     call var_list_synchronize (local%var_list, &
          model_get_var_list_ptr (local%model), reset_pointers = .true.)
     call local%particle_stack%init (local%model)
  end if
  if (associated (global%prclib)) then
     local%prclib => &
          local%prclib_stack%get_library_ptr (global%prclib%get_name ())
  end if
  local%it_list = global%it_list
  local%beam_structure = global%beam_structure
  local%lhapdf_status = global%lhapdf_status
  local%pn = global%pn
  if (allocated (local%sample_fmt))  deallocate (local%sample_fmt)
  if (allocated (global%sample_fmt)) then
     allocate (local%sample_fmt (size (global%sample_fmt)), &
          source = global%sample_fmt)
  end if
  local%out_files => global%out_files
 end subroutine rt_data_link
```

Restore the previous state of data; in particular, the variable list. This applies only to model variables (which are copies); other variables are automatically restored when local variables are removed.

If the `keep_local` flag is set, we want to retain current settings in the local environment. In particular, we create an instance of the currently selected model (which thus becomes separated from the model library!), and we synchronize the local variable list with it. The other local variables are also kept.

Some command (`read_slha`) reads in model variables as local entities. In this case, the original values of model variables should not be restored, but the global variable list should be synchronized. However, this matters only if the local model is identical to the global model; otherwise, restoring will apply to a different model.

Finally, model list, process library stack, and process stack are copied back. Thus, they behave like global objects: all changes in the local environment are kept in the global context. Note that these are shallow copies.

⟨*RT data: rt data: TBP*⟩+≡
```
procedure :: restore => rt_data_restore
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_data_restore (global, local, keep_model_vars, keep_local)
  class(rt_data_t), intent(inout) :: global
  class(rt_data_t), intent(inout) :: local
  logical, intent(in), optional :: keep_model_vars, keep_local
  logical :: same_model, restore, delete
  delete = .true.;  if (present (keep_local))  delete = .not. keep_local
  if (delete) then
     call var_list_undefine (local%var_list, follow_link=.false.)
  else
     if (associated (local%model)) then
        call model_pointer_to_instance (local%model)
        call var_list_synchronize (local%var_list, &
             model_get_var_list_ptr (local%model), reset_pointers = .true.)
     end if
  end if
  if (associated (global%model)) then
     call local%particle_stack%restore_model ()
     same_model = &
         global%model%get_name () == local%model%get_name ()
     if (present (keep_model_vars) .and. same_model) then
        restore = .not. keep_model_vars
     else
        if (.not. same_model)  call msg_message ("Restoring model '" // &
             char (global%model%get_name ()) // "'")
        restore = .true.
     end if
     if (restore) then
        call var_list_restore (global%var_list)
     else
        call var_list_synchronize &
             (global%var_list, model_get_var_list_ptr (global%model))
     end if
  end if
  call global%restore_globals (local)
end subroutine rt_data_restore
```

This restores global objects, for which local modifications should be kept.

⟨*RT data: rt data: TBP*⟩+≡
```
procedure :: restore_globals => rt_data_restore_globals
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_data_restore_globals (global, local)
  class(rt_data_t), intent(inout) :: global
  class(rt_data_t), intent(in) :: local
  global%model_list = local%model_list
  global%prclib_stack = local%prclib_stack
  global%process_stack = local%process_stack
```

```
        end subroutine rt_data_restore_globals
```

22.3.8   Finalization

Finalizer for the variable list and the structure-function list. This is done only
for the global RT dataset; local copies contain pointers to this and do not need
a finalizer.

⟨*RT data: rt data: TBP*⟩+≡
```
    procedure :: final => rt_data_global_final
```

⟨*RT data: procedures*⟩+≡
```
    subroutine rt_data_global_final (global)
      class(rt_data_t), intent(inout) :: global
      call global%process_stack%final ()
      call global%prclib_stack%final ()
      call global%particle_stack%final ()
      call global%model_list%final ()
      call var_list_final (global%var_list)
      if (associated (global%out_files)) then
         call file_list_final (global%out_files)
         deallocate (global%out_files)
      end if
    end subroutine rt_data_global_final
```

The local copy needs a finalizer just for the variable list, which consists of local
copies.

⟨*RT data: rt data: TBP*⟩+≡
```
    procedure :: local_final => rt_data_local_final
```

⟨*RT data: procedures*⟩+≡
```
    subroutine rt_data_local_final (local)
      class(rt_data_t), intent(inout) :: local
      call var_list_final (local%var_list)
    end subroutine rt_data_local_final
```

22.3.9   Filling Contents

Read a model, filling the model list component and assigning this as the current
model. Copy the model variables to the global var list.

⟨*RT data: rt data: TBP*⟩+≡
```
    procedure :: read_model => rt_data_read_model
```

⟨*RT data: procedures*⟩+≡
```
    subroutine rt_data_read_model (global, name, filename, synchronize)
      class(rt_data_t), intent(inout) :: global
      type(string_t), intent(in) :: name, filename
      type(var_list_t), pointer :: model_vars
      logical, intent(in), optional :: synchronize
      logical :: sync
      sync = .true.;  if (present (synchronize))  sync = synchronize
      call global%model_list%read_model &
```

```
          (name, filename, global%os_data, global%model)
      if (associated (global%model)) then
         call var_list_set_string (global%var_list, var_str ("$model_name"), &
              name, is_known = .true.)
         model_vars => model_get_var_list_ptr (global%model)
         call var_list_init_copies (global%var_list, model_vars)
         if (sync) then
            call var_list_synchronize (global%var_list, model_vars, &
                 reset_pointers = .true.)
         end if
         call global%particle_stack%reset (global%model)
      end if
   end subroutine rt_data_read_model
```

Select a model, assuming that it has already been read.

⟨*RT data: rt data: TBP*⟩+≡
```
   procedure :: select_model => rt_data_select_model
```

⟨*RT data: procedures*⟩+≡
```
   subroutine rt_data_select_model (global, name)
     class(rt_data_t), intent(inout) :: global
     type(string_t), intent(in) :: name
     type(var_list_t), pointer :: model_vars
     global%model => global%model_list%get_model_ptr (name)
     if (associated (global%model)) then
        call var_list_set_string (global%var_list, var_str ("$model_name"), &
             name, is_known = .true.)
        model_vars => model_get_var_list_ptr (global%model)
        call var_list_synchronize (global%var_list, model_vars, &
             reset_pointers = .true.)
        call global%particle_stack%reset (global%model)
     end if
   end subroutine rt_data_select_model
```

Modify particle properties. If necessary, we save the old status in the `particle_stack`
subobject, then modify the entry in the local model directly.

⟨*RT data: rt data: TBP*⟩+≡
```
   procedure :: modify_particle => rt_data_modify_particle
```

⟨*RT data: procedures*⟩+≡
```
   subroutine rt_data_modify_particle &
        (global, pdg, polarized, stable, decay, isotropic_decay, diagonal_decay)
     class(rt_data_t), intent(inout) :: global
     integer, intent(in) :: pdg
     logical, intent(in), optional :: polarized, stable
     logical, intent(in), optional :: isotropic_decay, diagonal_decay
     type(string_t), dimension(:), intent(in), optional :: decay
     if (.not. global%particle_stack%contains (pdg)) then
        call global%particle_stack%push (pdg)
     end if
     if (present (polarized)) then
        if (polarized) then
           call model_set_polarized (global%model, pdg)
        else
```

```
         call model_set_unpolarized (global%model, pdg)
      end if
   end if
   if (present (stable)) then
      if (stable) then
         call model_set_stable (global%model, pdg)
      else if (present (decay)) then
         call model_set_unstable &
              (global%model, pdg, decay, isotropic_decay, diagonal_decay)
      else
         call msg_bug ("Setting particle unstable: missing decay processes")
      end if
   end if
end subroutine rt_data_modify_particle
```

Add a library (available via a pointer of type `prclib_entry_t`) to the stack and update the pointer and variable list to the current library. The pointer association of `prclib_entry` will be discarded.

⟨*RT data: rt data: TBP*⟩+≡
```
   procedure :: add_prclib => rt_data_add_prclib
```

⟨*RT data: procedures*⟩+≡
```
   subroutine rt_data_add_prclib (global, prclib_entry)
     class(rt_data_t), intent(inout) :: global
     type(prclib_entry_t), intent(inout), pointer :: prclib_entry
     call global%prclib_stack%push (prclib_entry)
     call global%update_prclib (global%prclib_stack%get_first_ptr ())
   end subroutine rt_data_add_prclib
```

Given a pointer to a process library, make this the currently active library.

⟨*RT data: rt data: TBP*⟩+≡
```
   procedure :: update_prclib => rt_data_update_prclib
```

⟨*RT data: procedures*⟩+≡
```
   subroutine rt_data_update_prclib (global, lib)
     class(rt_data_t), intent(inout) :: global

    end if
  end associate
end subroutine rt_data_show_beams
```

Return the collision energy as determined by the current beam settings. Without beam setup, this is the `sqrts` variable.

If the value is meaningless for a setup, the function returns zero.

⟨*RT data: rt data: TBP*⟩+≡
```
procedure :: get_sqrts => rt_data_get_sqrts
```

⟨*RT data: procedures*⟩+≡
```
function rt_data_get_sqrts (rt_data) result (sqrts)
  class(rt_data_t), intent(in) :: rt_data
  real(default) :: sqrts
  sqrts = var_list_get_rval (rt_data%var_list, var_str ("sqrts"))
end function rt_data_get_sqrts
```

For testing purposes, the `rt_data_t` contents can be pacified to suppress numerical fluctuations in (constant) test matrix elements.

⟨*RT data: rt data: TBP*⟩+≡
```
procedure :: pacify => rt_data_pacify
```

⟨*RT data: procedures*⟩+≡
```
subroutine rt_data_pacify (rt_data, efficiency_reset, error_reset)

  do while (associated (process))
     call process%pacify (efficiency_reset, error_reset)
     process => process%next
  end do
end subroutine rt_data_pacify
```

22.3.11   Test

This is the master for calling self-test procedures.

⟨*RT data: public*⟩+≡
```
public :: rt_data_test
```

⟨*RT data: tests*⟩≡
```
subroutine rt_data_test (u, results)
  integer, intent(in) :: u
  type(test_results_t), intent(inout) :: results
```
⟨*RT data: execute tests*⟩
```
end subroutine rt_data_test
```

Initial content

Force system-dependent objects to well-defined values. Some of the variables are locked and therefore must be addressed directly.

This is, of course, only required for testing purposes. In principle, the `real_specimen` variables could be set to their values in `rt_data_t`, but this depends on the precision again, so we set them to some dummy values.

⟨*RT data: rt data: TBP*⟩+≡

      write (u, "(A)")  "* Test output end: rt_data_2"

    end subroutine rt_data_2
```

Save and restore

Set up a local runtime data block, change some contents, restore the global block.

For a model variable, the save-restore procedure is nontrivial. We first allocate a local copy of this variable and set a pointer to the original model variable. We set a new value, update the dependent variables and synchronize them with the local variable list, if modified. When restoring the old data, we recover the model variables from the stored values and delete the local instances.

⟨*RT data: execute tests*⟩+≡
```
    call test (rt_data_3, "rt_data_3", &
         "save/restore", &
         u, results)

```

Local Model

Locally modify a model and restore the global one. We need an auxiliary function to determine the status of a model particle:

⟨RT data: tests⟩+≡
```
function is_stable (pdg, rt_data) result (flag)
  integer, intent(in) :: pdg
  type(rt_data_t), intent(in) :: rt_data
  logical :: flag
  type(flavor_t) :: flv
  call flavor_init (flv, pdg, rt_data%model)
  flag = flavor_is_stable (flv)
end function is_stable

function is_polarized (pdg, rt_data) result (flag)
  integer, intent(in) :: pdg
  type(rt_data_t), intent(in) :: rt_data
  logical :: flag
```

```
      type(flavor_t) :: flv
      call flavor_init (flv, pdg, rt_data%model)
      flag = flavor_is_polarized (flv)
    end function is_polarized
```

⟨*RT data: execute tests*⟩+≡
```
    call test (rt_data_6, "rt_data_6", &
         "local model", &
         u, results)
```
⟨*RT data: tests*⟩+≡
```
    subroutine rt_data_6 (u)
      integer, intent(in) :: u
      type(rt_data_t), target :: rt_data, local

    write (u, "(A)")
    write (u, "(A)")  "* Test output end: rt_data_8"

  end subroutine rt_data_8
```

22.4 Select implementations

For abstract types (process core, integrator, phase space, etc.), we need a way to dynamically select a concrete type, using either data given by the user or a previous selection of a concrete type. This is done by subroutines in the current module.

This module provides no new types, just procedures.

⟨dispatch.f90⟩≡
  ⟨*File header*⟩

22.4.1   Process Core Definition

The `prc_core_def_t` abstract type can be instantiated by providing a `$method`
string variable.

Note: `core_def` has intent(inout) because gfortran 4.7.1 crashes for intent(out).

⟨*Dispatch: public*⟩≡
```
    public :: dispatch_core_def
```

⟨*Dispatch: procedures*⟩≡
```
    subroutine dispatch_core_def (core_def, prt_in, prt_out, global)
      class(prc_core_def_t), allocatable, intent(inout) :: core_def
      type(string_t), dimension(:), intent(in) :: prt_in
      type(string_t), dimension(:), intent(in) :: prt_out
      type(rt_data_t), intent(in) :: global
      type(string_t) :: method
      type(string_t) :: model_name
      type(string_t) :: restrictions
      logical :: openmp_support
      logical :: report_progress
      logical :: diags, diags_color
```

2829

```fortran
    type(string_t) :: extra_options
    type(model_t), pointer :: model
    model => global%model
    associate (var_list => global%var_list)
      method = var_list_get_sval (var_list, var_str ("$method"))
      model_name = var_list_get_sval (var_list, var_str ("$model_name"))
      select case (char (method))
      case ("unit_test")
         allocate (prc_test_def_t :: core_def)
         select type (core_def)
         type is (prc_test_def_t)
            call core_def%init (model_name, prt_in, prt_out)
         end select
      case ("template")

      end select
    end associate
  end subroutine dispatch_core_def
```

22.4.2 Process core allocation

Here we allocate an object of abstract type `prc_core_t` with a concrete type that matches a process definition. The `prc_omega_t` extension will require the current parameter set, so we take the opportunity to grab it from the model.

⟨*Dispatch: public*⟩+≡
```
    public :: dispatch_core
```

⟨*Dispatch: procedures*⟩+≡
```
    subroutine dispatch_core (core, core_def, model, &
        helicity_selection, qcd, use_color_factors)
      class(prc_core_t), allocatable, intent(inout) :: core
      class(prc_core_def_t), intent(in) :: core_def
      type(model_t), intent(in), target, optional :: model
      type(helicity_selection_t), intent(in), optional :: helicity_selection
      type(qcd_t), intent(in), optional :: qcd
      logical, intent(in), optional :: use_color_factors
      select type (core_def)
      type is (prc_test_def_t)
         allocate (test_t :: core)
      type is (template_me_def_t)
         allocate (prc_template_me_t :: core)
         select type (core)

22.4.3 Process core update and restoration

Here we take an existing object of abstract type `prc_core_t` and update the parameters as given by the current state of `model`. Optionally, we can save the previous state as `saved_core`. The second routine restores the original from the save.

(In the test case, there is no possible update.)

        end select
     end subroutine dispatch_phs
```

22.4.6   Random-number generator

Allocate a random-number generator factory according to the variable `$rng_method`, using the current seed in the global record. We take only the lower 15 bits of the seed, so the actual value fits into a positive 16-bit signed integer.

Since we want to guarantee that all random-number generators in a run are independent, we increment the global seed by one after creating the rng factory. If the user wants to have identical sequences, he can always set the seed manually, before it is used.

⟨*Dispatch: public*⟩+≡
```
    public :: dispatch_rng_factory
```

⟨*Dispatch: procedures*⟩+≡
```
    subroutine dispatch_rng_factory (rng_factory, global)
      class(rng_factory_t), allocatable, intent(out) :: rng_factory
      type(rt_data_t), intent(inout) :: global
      type(string_t) :: rng_method
      integer :: seed
      character(30) :: buffer
      integer(i16) :: s
      rng_method = var_list_get_sval (global%var_list, var_str ("$rng_method"))
      seed = var_list_get_ival (global%var_list, var_str ("seed"))
      s = mod (seed, 32768)
      select case (char (rng_method))
```

```
      case ("unit_test")
         allocate (rng_test_factory_t :: rng_factory)
         call msg_message ("RNG: Initializing Test random-number generator")
      case ("tao")

      end select
      write (buffer, "(I0)")  s
      call msg_message ("RNG: Setting seed for random-number generator to " &
            // trim (buffer))
      call rng_factory%init (s)
      call var_list_set_int (global%var_list, var_str ("seed"), seed + 1, &
            is_known = .true.)
    end subroutine dispatch_rng_factory
```

22.4.7 Structure function configuration data

This data type is a container for transferring structure-function specific data
from the `dispatch_sf_data` to the `dispatch_sf_channels` subroutine.

⟨*Dispatch: public*⟩+≡
```
    public :: sf_prop_t
```

⟨*Dispatch: types*⟩≡
```
    type :: sf_prop_t
       real(default), dimension(2) :: isr_eps = 1
    end type sf_prop_t
```

Allocate a structure-function configuration object according to the `sf_method`
string.

The `sf_prop` object can be used to transfer structure-function specific data
up and to the `dispatch_sf_channels` subroutine below, so they can be used
for particular mappings.

The `global` object is intent(inout) because the PDF status may change
during initialization.

The `pdg_in` array is the array of incoming flavors, corresponding to the up-
stream structure function or the beam array. This will be checked for the struc-
ture function in question and replaced by the outgoing flavors. The `pdg_prc`
array is the array of incoming flavors (beam index, component index) for the
hard process.

⟨*Dispatch: public*⟩+≡
```
    public :: dispatch_sf_data
```

⟨*Dispatch: procedures*⟩+≡
```

```

This is an auxiliary procedure, used by the beam-structure expansion: tell for a given structure function name, whether it corresponds to a pair spectrum ($n = 2$), a single-particle structure function ($n = 1$), or nothing ($n = 0$). Though `energy_scan` can in principle also be a pair spectrum, it always has only one parameter.

⟨*Dispatch: procedures*⟩+≡
```
   function strfun_mode (name) result (n)
     type(string_t), intent(in) :: name
     integer :: n
     select case (char (name))

        n = 2
     case ("beam_events")
        n = 2
     case ("energy_scan")
        n = 2
     case default
        call msg_bug ("Structure function '" // char (name) &
              // "' not supported yet")
     end select
   end function strfun_mode
```

Dispatch a whole structure-function chain, given beam data and beam structure data.

This could be done generically, but we should look at the specific combination of structure functions in order to select appropriate mappings.

The `beam_structure` argument gets copied because we want to expand it to canonical form (one valid structure-function entry per record) before proceeding further.

The `pdg_prc` argument is the array of incoming flavors. The first index is the beam index, the second one the process component index. Each element is itself a PDG array, notrivial if there is a flavor sum for the incoming state of this component.

The dispatcher is divided in two parts. The first part configures the structure function data themselves. After this, we can configure the phase space for the

2842

elementary process.

⟨*Dispatch: public*⟩+≡

```
    public :: dispatch_sf_config
```

⟨*Dispatch: procedures*⟩+≡

```
    subroutine dispatch_sf_config (sf_config, sf_prop, global, pdg_prc)
      type(sf_config_t), dimension(:), allocatable, intent(out) :: sf_config
      type(sf_prop_t), intent(out) :: sf_prop

      type(pdg_array_t), dimension(:,:), intent(in) :: pdg_prc
      type(string_t), dimension(:), allocatable :: prt_in
      type(pdg_array_t), dimension(:), allocatable :: pdg_in
      type(flavor_t) :: flv_in
      integer :: n_beam, n_record, i
      beam_structure = global%beam_structure
      call beam_structure%expand (strfun_mode)
      n_record = beam_structure%get_n_record ()
      allocate (sf_config (n_record))
      n_beam = beam_structure%get_n_beam ()
      if (n_beam > 0) then
         allocate (prt_in (n_beam), pdg_in (n_beam))
         prt_in = beam_structure%get_prt ()
         do i = 1, n_beam
            call flavor_init (flv_in, prt_in(i), global%model)
            pdg_in(i) = flavor_get_pdg (flv_in)
         end do
      else
         n_beam = size (pdg_prc, 1)
         allocate (pdg_in (n_beam))
         pdg_in = pdg_prc(:,1)
      end if
      do i = 1, n_record
         call dispatch_sf_data (sf_data, &
              beam_structure%get_name (i), &
              beam_structure%get_i_entry (i), &
              sf_prop, global, pdg_in, pdg_prc)
         call sf_config(i)%init (beam_structure%get_i_entry (i), sf_data)
         deallocate (sf_data)
      end do
    end subroutine dispatch_sf_config
```

The second part configures channel mappings, using some conditions from the
phase space configuration. If there are no structure functions, we enable a
default setup with a single (dummy) structure-function channel. Otherwise, we
look at the channel collection that we got from the phase-space configuration
step. Each entry should be translated into an independent structure-function
channel, where typically there is one default entry, which could be mapped using
a standard s-channel mapping if the structure function setup recommends this,
and other entries with s-channel resonances. The latter need to be translated
into global mappings from the structure-function chain.

22.4.9 QCD coupling

Allocate the `alpha` (running coupling) component of the `qcd` block with a concrete implementation, depending on the variable settings in the `global` record.

If a fixed α_s is requested, we do not allocate the `qcd%alpha` object. In this case, the matrix element code will just take the model parameter as-is, which implies fixed α_s. If the object is allocated, the α_s value is computed and updated for each matrix-element call.

⟨*Dispatch: public*⟩+≡

```

22.5 Process Configuration

This module communicates between the toplevel command structure with its
runtime data set and the process-library handling modules which collect the
definition of individual processes. Its primary purpose is to select from the
available matrix-element generating methods and configure the entry in the
process library accordingly.

⟨process_configurations.f90⟩≡
  ⟨*File header*⟩

```
  module process_configurations
```

  ⟨*Use strings*⟩
```
    use diagnostics !NODEP!
    use unit_tests
    use variables
    use models
    use prc_core_def
    use particle_specifiers
    use process_libraries
    use prclib_stacks
    use prc_test
    use prc_omega
    use rt_data
    use dispatch
```

  ⟨*Standard module head*⟩

  ⟨*Process configurations: public*⟩

  ⟨*Process configurations: types*⟩

```
  contains
```

⟨*Process configurations: procedures*⟩

⟨*Process configurations: tests*⟩

```
end module process_configurations
```

22.5.1 Data Type

⟨*Process configurations: public*⟩≡
```
    public :: process_configuration_t
```

⟨*Process configurations: types*⟩≡
```
    type :: process_configuration_t
      type(process_def_entry_t), pointer :: entry => null ()
      type(string_t) :: id
      integer :: num_id = 0
     contains
```
    ⟨*Process configurations: process configuration: TBP*⟩
```
    end type process_configuration_t
```

Initialize a process. We only need the name, the number of incoming particles, and the number of components.

⟨*Process configurations: process configuration: TBP*⟩≡
```
    procedure :: init => process_configuration_init
```

⟨*Process configurations: procedures*⟩≡
```
    subroutine process_configuration_init &
        (config, prc_name, n_in, n_components, global)
      class(process_configuration_t), intent(out) :: config
      type(string_t), intent(in) :: prc_name
      integer, intent(in) :: n_in
      integer, intent(in) :: n_components
      type(rt_data_t), intent(in) :: global
      type(model_t), pointer :: model
      model => global%model
      config%id = prc_name
      allocate (config%entry)
      if (var_list_is_known (global%var_list, var_str ("process_num_id"))) then
         config%num_id = &
              var_list_get_ival (global%var_list, var_str ("process_num_id"))
         call config%entry%init (prc_name, &
              model = model, n_in = n_in, n_components = n_components, &
              num_id = config%num_id)
      else
         call config%entry%init (prc_name, &
              model = model, n_in = n_in, n_components = n_components)
      end if
    end subroutine process_configuration_init
```

Initialize a process component. The details depend on the process method, which determines the type of the process component core. We set the incoming and outgoing particles (as strings, to be interpreted by the process driver). All other information is taken from the variable list.

2879

The dispatcher gets only the names of the particles. The process component definition gets the complete specifiers which contains a polarization flag and names of decay processes, where applicable.

⟨*Process configurations: process configuration: TBP*⟩+≡
```
    procedure :: setup_component => process_configuration_setup_component
```

⟨*Process configurations: procedures*⟩+≡
```
    subroutine process_configuration_setup_component &
        (config, i_component, prt_in, prt_out, global)
      class(process_configuration_t), intent(inout) :: config
      integer, intent(in) :: i_component
      type(prt_spec_t), dimension(:), intent(in) :: prt_in
      type(prt_spec_t), dimension(:), intent(in) :: prt_out
      type(rt_data_t), intent(in) :: global
      type(string_t), dimension(:), allocatable :: prt_str_in
      type(string_t), dimension(:), allocatable :: prt_str_out
      class(prc_core_def_t), allocatable :: core_def
      type(string_t) :: method
      integer :: i
      allocate (prt_str_in  (size (prt_in)))
      allocate (prt_str_out (size (prt_out)))
      forall (i = 1:size (prt_in))  prt_str_in(i)  = prt_in(i)% get_name ()

                 config%num_id, ")"
         else
            write (msg_buffer, "(5A)") "Process library '", &
                 char (global%prclib%get_name ()), &
                 "': recorded process '", char (config%id), "'"
```

```
      end if
      call msg_message ()
   else
      call msg_fatal ("Recording process '" // char (config%id) &
            // "': active process library undefined")
   end if
end subroutine process_configuration_record
```

22.5.2 Test

This is the master for calling self-test procedures.

⟨*Process configurations: public*⟩+≡
```
   public :: process_configurations_test
```

⟨*Process configurations: tests*⟩≡
```
   subroutine process_configurations_test (u, results)
     integer, intent(in) :: u
     type(test_results_t), intent(inout) :: results
   ⟨Process configurations: execute tests⟩
 end subroutine process_configurations_test
```

Minimal setup

The workflow for setting up a minimal process configuration with the test matrix element method.

We wrap this in a public procedure, so we can reuse it in later modules. The procedure prepares a process definition list for two processes (one `prc_test` and one `omega` type) and appends this to the process library stack in the global data set.

The `mode` argument determines which processes to build.

The `procname` argument replaces the predefined procname(s).

⟨*Process configurations: public*⟩+≡
```
   public :: prepare_test_library
```

⟨*Process configurations: tests*⟩+≡
```
   subroutine prepare_test_library (global, libname, mode, procname)
     type(rt_data_t), intent(inout), target :: global
     type(string_t), intent(in) :: libname
     integer, intent(in) :: mode
     type(string_t), intent(in), dimension(:), optional :: procname

     type(prclib_entry_t), pointer :: lib
     type(string_t) :: prc_name
     type(string_t), dimension(:), allocatable :: prt_in, prt_out

    end subroutine process_configurations_2
```

22.6 Compilation

This module manages compilation and loading of of process libraries. It is
needed as a separate module because integration depends on it.

⟨compilations.f90⟩≡
  ⟨*File header*⟩

```
  module compilations
```

  ⟨*Use strings*⟩
  ⟨*Use file utils*⟩
```
    use diagnostics !NODEP!
    use limits, only: TAB !NODEP!
    use os_interface
    use unit_tests
    use md5
    use variables
    use models
    use process_libraries
    use prclib_stacks
    use rt_data
    use process_configurations
```

  ⟨*Standard module head*⟩

  ⟨*Compilations: public*⟩

  ⟨*Compilations: types*⟩

```
  contains
```

  ⟨*Compilations: procedures*⟩

  ⟨*Compilations: tests*⟩

```
  end module compilations
```

22.6.1 The data type

The compilation item handles the compilation and loading of a single process library.

⟨*Compilations: types*⟩≡

```
    type :: compilation_item_t
      type(string_t) :: libname
      type(process_library_t), pointer :: lib => null ()
      logical :: recompile_library = .false.
    contains
    ⟨Compilations: compilation item: TBP⟩
    end type compilation_item_t
```

Initialize:

⟨*Compilations: compilation item: TBP*⟩≡

```
    procedure :: init => compilation_item_init
```

⟨*Compilations: procedures*⟩≡

```
    subroutine compilation_item_init (comp, libname, stack, var_list)
      class(compilation_item_t), intent(out) :: comp
      type(string_t), intent(in) :: libname
      type(prclib_stack_t), intent(inout) :: stack
      type(var_list_t), intent(in) :: var_list
      comp%libname = libname
      comp%lib => stack%get_library_ptr (comp%libname)
      if (.not. associated (comp%lib)) then
         call msg_fatal ("Process library '" // char (comp%libname) &
               // "' has not been declared.")
      end if
      comp%recompile_library = &
            var_list_get_lval (var_list, var_str ("?recompile_library"))
    end subroutine compilation_item_init
```

Compile the current library. The `force` flag has the effect that we first delete any previous files, as far as accessible by the current makefile. It also guarantees that previous files not accessible by a makefile will be overwritten.

⟨*Compilations: compilation item: TBP*⟩+≡

```
    procedure :: compile => compilation_item_compile
```

⟨*Compilations: procedures*⟩+≡

```
    subroutine compilation_item_compile (comp, os_data, force, recompile)
      class(compilation_item_t), intent(inout) :: comp
      type(os_data_t), intent(in) :: os_data
      logical, intent(in) :: force, recompile
      if (associated (comp%lib)) then
         call msg_message ("Process library '" &
               // char (comp%libname) // "': compiling ...")
         call comp%lib%configure (os_data)
         if (signal_is_pending ())  return
         call comp%lib%compute_md5sum ()
         call comp%lib%write_makefile (os_data, force)
         if (signal_is_pending ())  return
         if (force) then
            call comp%lib%clean (os_data, distclean = .false.)
```

```
            if (signal_is_pending ())  return
         end if
         call comp%lib%write_driver (force)
         if (signal_is_pending ())  return
         if (recompile) then
            call comp%lib%load (os_data, keep_old_source = .true.)
            if (signal_is_pending ())  return
         end if
         call comp%lib%update_status (os_data)
      end if
    end subroutine compilation_item_compile
```

Load the current library, just after compiling it.

⟨*Compilations: compilation item: TBP*⟩+≡
```
    procedure :: load => compilation_item_load
```

⟨*Compilations: procedures*⟩+≡
```
    subroutine compilation_item_load (comp, os_data)
      class(compilation_item_t), intent(inout) :: comp
      type(os_data_t), intent(in) :: os_data
      if (associated (comp%lib)) then
         call comp%lib%load (os_data)
      end if
    end subroutine compilation_item_load
```

Message as a separate call:

⟨*Compilations: compilation item: TBP*⟩+≡
```
    procedure :: success => compilation_item_success
```

⟨*Compilations: procedures*⟩+≡
```
    subroutine compilation_item_success (comp)
      class(compilation_item_t), intent(in) :: comp
      if (associated (comp%lib)) then
         call msg_message ("Process library '" // char (comp%libname) &
               // "': ... success.")
      end if
    end subroutine compilation_item_success
```

22.6.2   API for library compilation and loading

This is a shorthand for compiling and loading a single library. The `compilation_item`
object is used only internally.

The `global` data set may actually be local to the caller. The compilation
affects the library specified by its name if it is on the stack, but it does not reset
the currently selected library.

⟨*Compilations: public*⟩≡
```
    public :: compile_library
```

⟨*Compilations: procedures*⟩+≡
```
    subroutine compile_library (libname, global)
      type(string_t), intent(in) :: libname
      type(rt_data_t), intent(inout), target :: global
```

```
      type(compilation_item_t) :: comp
      logical :: force, recompile
      force = &
           var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
      recompile = &
           var_list_get_lval (global%var_list, var_str ("?recompile_library"))
      call comp%init (libname, global%prclib_stack, global%var_list)
      call comp%compile (global%os_data, force, recompile)
      if (signal_is_pending ())  return
      call comp%load (global%os_data)
      if (signal_is_pending ())  return
      call comp%success ()
    end subroutine compile_library
```

22.6.3   Compiling static executable

This object handles the creation of a static executable which should contain a
set of static process libraries.

⟨*Compilations: types*⟩+≡
```
    type :: compilation_t
      private
      type(string_t) :: exe_name
      type(string_t), dimension(:), allocatable :: lib_name
     contains
     ⟨Compilations: compilation: TBP⟩
    end type compilation_t
```

Output.

⟨*Compilations: compilation: TBP*⟩≡
```
    procedure :: write => compilation_write
```

⟨*Compilations: procedures*⟩+≡
```
    subroutine compilation_write (object, unit)
      class(compilation_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u, i
      u = output_unit (unit)
      write (u, "(1x,A)")  "Compilation object:"
      write (u, "(3x,3A)")  "executable       = '", &
           char (object%exe_name), "'"
      write (u, "(3x,A)", advance="no")  "process libraries ="
      do i = 1, size (object%lib_name)
         write (u, "(1x,3A)", advance="no")  "'", char (object%lib_name(i)), "'"
      end do
      write (u, *)
    end subroutine compilation_write
```

Initialize: we know the names of the executable and of the libraries.

⟨*Compilations: compilation: TBP*⟩+≡
```
    procedure :: init => compilation_init
```

⟨*Compilations: procedures*⟩+≡

```
subroutine compilation_init (compilation, exe_name, lib_name)
  class(compilation_t), intent(out) :: compilation
  type(string_t), intent(in) :: exe_name
  type(string_t), dimension(:), intent(in) :: lib_name
  compilation%exe_name = exe_name
  allocate (compilation%lib_name (size (lib_name)))
  compilation%lib_name = lib_name
end subroutine compilation_init
```

Write the dispatcher subroutine for the compiled libraries. Also write a subrou-
tine which returns the names of the compiled libraries.

⟨*Compilations: compilation: TBP*⟩+≡

```
procedure :: write_dispatcher => compilation_write_dispatcher
```

⟨*Compilations: procedures*⟩+≡

```
subroutine compilation_write_dispatcher (compilation)
  class(compilation_t), intent(in) :: compilation
  type(string_t) :: file
  integer :: u, i
  file = compilation%exe_name // "_prclib_dispatcher.f90"
  call msg_message ("Static executable '" // char (compilation%exe_name) &
       // "': writing library dispatcher")
  u = free_unit ()
  open (u, file = char (file), status="replace", action="write")
  write (u, "(3A)")  "! Whizard: process libraries for executable '", &
       char (compilation%exe_name), "'"
  write (u, "(A)")  "! Automatically generated file, do not edit"
  write (u, "(A)")  "subroutine dispatch_prclib_static " // &
       "(driver, basename, modellibs_ldflags)"
  write (u, "(A)")  "  use iso_varying_string, string_t => varying_string"
  write (u, "(A)")  "  use prclib_interfaces"
  do i = 1, size (compilation%lib_name)
     associate (lib_name => compilation%lib_name(i))
       write (u, "(A)")  "  use " // char (lib_name) // "_driver"
     end associate
  end do
  write (u, "(A)")  "  implicit none"
  write (u, "(A)")  "  class(prclib_driver_t), intent(inout), allocatable &
       &:: driver"
  write (u, "(A)")  "  type(string_t), intent(in) :: basename"
  write (u, "(A)")  "  logical, intent(in), optional :: " // &
       "modellibs_ldflags"
  write (u, "(A)")  "  select case (char (basename))"
  do i = 1, size (compilation%lib_name)
     associate (lib_name => compilation%lib_name(i))
       write (u, "(3A)")  "  case ('", char (lib_name), "')"
       write (u, "(3A)")  "     allocate (", char (lib_name), "_driver_t &
            &:: driver)"
     end associate
  end do
  write (u, "(A)")  "  end select"
  write (u, "(A)")  "end subroutine dispatch_prclib_static"
  write (u, *)
```

```
      write (u, "(A)")  "subroutine get_prclib_static (libname)"
      write (u, "(A)")  "  use iso_varying_string, string_t => varying_string"
      write (u, "(A)")  "  implicit none"

       write (u, "(A)") ".PHONY: clean distclean"
       close (u)
  end subroutine compilation_write_makefile
```

Compile the dispatcher source code.

⟨*Compilations: compilation: TBP*⟩+≡

```
    procedure :: make_compile => compilation_make_compile
```

⟨*Compilations: procedures*⟩+≡
```
    subroutine compilation_make_compile (compilation, os_data)
      class(compilation_t), intent(in) :: compilation
      type(os_data_t), intent(in) :: os_data
      call os_system_call ("make compile " // os_data%makeflags &
          // " -f " // compilation%exe_name // ".makefile")
    end subroutine compilation_make_compile
```

Link the dispatcher together with all matrix-element code and the WHIZARD and
O'MEGA main libraries, to generate a static executable.

⟨*Compilations: compilation: TBP*⟩+≡
```
    procedure :: make_link => compilation_make_link
```

⟨*Compilations: procedures*⟩+≡
```
    subroutine compilation_make_link (compilation, os_data)
      class(compilation_t), intent(in) :: compilation
      type(os_data_t), intent(in) :: os_data
      call os_system_call ("make link " // os_data%makeflags &
          // " -f " // compilation%exe_name // ".makefile")
    end subroutine compilation_make_link
```

Cleanup.

⟨*Compilations: compilation: TBP*⟩+≡
```
    procedure :: make_clean_exe => compilation_make_clean_exe
```

⟨*Compilations: procedures*⟩+≡
```
    subroutine compilation_make_clean_exe (compilation, os_data)
      class(compilation_t), intent(in) :: compilation
      type(os_data_t), intent(in) :: os_data
      call os_system_call ("make clean-exe " // os_data%makeflags &
          // " -f " // compilation%exe_name // ".makefile")
    end subroutine compilation_make_clean_exe
```

22.6.4   API for executable compilation

This is a shorthand for compiling and loading an executable, including the
enclosed libraries. The `compilation` object is used only internally.

The `global` data set may actually be local to the caller. The compilation
affects the library specified by its name if it is on the stack, but it does not reset
the currently selected library.

⟨*Compilations: public*⟩+≡
```
    public :: compile_executable
```

⟨*Compilations: procedures*⟩+≡
```
    subroutine compile_executable (exename, libname, global)
      type(string_t), intent(in) :: exename
      type(string_t), dimension(:), intent(in) :: libname
      type(rt_data_t), intent(inout), target :: global
      type(compilation_t) :: compilation
      type(compilation_item_t) :: item
```

```
logical :: force, recompile
integer :: i
force = &
     var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
recompile = &
     var_list_get_lval (global%var_list, var_str ("?recompile_library"))
call compilation%init (exename, [libname])
if (signal_is_pending ())  return
call compilation%write_dispatcher ()
if (signal_is_pending ())  return
call compilation%write_makefile (global%os_data)
if (signal_is_pending ())  return
do i = 1, size (libname)
   call item%init (libname(i), global%prclib_stack, global%var_list)
   call item%compile (global%os_data, force=force, recompile=recompile)
   if (signal_is_pending ())  return
   call item%success ()
end do
call compilation%make_compile (global%os_data)
if (signal_is_pending ())  return
call compilation%make_link (global%os_data)
end subroutine compile_executable
```

22.6.5   Test

This is the master for calling self-test procedures.

⟨*Compilations: public*⟩+≡
```
public :: compilations_test
```

⟨*Compilations: tests*⟩≡
```
subroutine compilations_test (u, results)
  integer, intent(in) :: u
  type(test_results_t), intent(inout) :: results
⟨Compilations: execute tests⟩
end subroutine compilations_test
```

Intrinsic Matrix Element

Compile an intrinsic test matrix element (`prc_test` type).

   Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

⟨*Compilations: execute tests*⟩≡
```
call test (compilations_1, "compilations_1", &
     "intrinsic test processes", &
     u, results)
```

⟨*Compilations: tests*⟩+≡
```
subroutine compilations_1 (u)
  integer, intent(in) :: u
  type(string_t) :: libname, procname
  type(rt_data_t), target :: global
```

```
      write (u, "(A)")   "* Test output: compilations_1"
      write (u, "(A)")   "*   Purpose: configure and compile test process"
      write (u, "(A)")

      call syntax_model_file_init ()

      call global%global_init ()

      libname = "compilation_1"
      procname = "prc_comp_1"
      call prepare_test_library (global, libname, 1, [procname])

      call compile_library (libname, global)

      call global%write_libraries (u)

      call global%final ()
      call syntax_model_file_final ()

      write (u, "(A)")

```

22.6.6 Test static build

The tests for building a static executable are separate, since they should be skipped if the WHIZARD build itself has static libraries disabled.

⟨*Compilations: public*⟩+≡
```
    public :: compilations_static_test
```

⟨*Compilations: tests*⟩+≡
```
    subroutine compilations_static_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
    ⟨Compilations: static tests⟩
  end subroutine compilations_static_test
```

External Matrix Element

Compile an external test matrix element (omega type) and incorporate this in a new static WHIZARD executable.

⟨*Compilations: static tests*⟩≡
```
    call test (compilations_static_1, "compilations_static_1", &
        "static executable: compilation", &
        u, results)
```

⟨*Compilations: tests*⟩+≡
```
    subroutine compilations_static_1 (u)
      integer, intent(in) :: u
      type(string_t) :: libname, procname, exename
      type(rt_data_t), target :: global
      type(compilation_item_t) :: item
      type(compilation_t) :: compilation
      logical :: exist

      write (u, "(A)")  "* Test output: compilations_static_1"
      write (u, "(A)")  "*   Purpose: make static executable"
      write (u, "(A)")

      write (u, "(A)")  "* Initialize library"

    call compilation%make_clean_exe (global%os_data)

    call global%final ()
    call syntax_model_file_final ()

    write (u, "(A)")
    write (u, "(A)")  "* Test output end: compilations_static_1"

  end subroutine compilations_static_1
```

External Matrix Element

Compile an external test matrix element (`omega` type) and incorporate this in a new static WHIZARD executable. In this version, we use the wrapper `compile_executable` procedure.

⟨*Compilations: static tests*⟩+≡
```
    call test (compilations_static_2, "compilations_static_2", &
         "static executable: shortcut", &
         u, results)
```

⟨*Compilations: tests*⟩+≡
```
    subroutine compilations_static_2 (u)
      integer, intent(in) :: u
      type(string_t) :: libname, procname, exename
      type(rt_data_t), target :: global
      type(compilation_item_t) :: item
      type(compilation_t) :: compilation
      logical :: exist
      integer :: u_file

      write (u, "(A)")  "* Test output: compilations_static_2"
      write (u, "(A)")  "*   Purpose: make static executable"
      write (u, "(A)")

      write (u, "(A)")  "* Initialize library and compile"
      write (u, "(A)")

      call syntax_model_file_init ()

      call global%global_init ()
      call var_list_set_log (global%var_list, var_str ("?omega_openmp"), &
           .false., is_known = .true.)

      libname = "compilations_static_2_lib"
      procname = "prc_comp_stat_2"
      exename = "compilations_static_2"

      call prepare_test_library (global, libname, 2, [procname,procname])

      call compile_executable (exename, [libname], global)

      write (u, "(A)")  "* Check executable (should be present)"
      write (u, "(A)")

      inquire (file = char (exename), exist = exist)
      write (u, "(A,A,L1)")  char (exename), " exists = ", exist

      write (u, "(A)")
      write (u, "(A)")  "* Cleanup"

      u_file = free_unit ()
      open (u_file, file = char (exename), status = "old", action = "write")
      close (u_file, status = "delete")

      call global%final ()
```

```
    call syntax_model_file_final ()

    write (u, "(A)")
    write (u, "(A)")  "* Test output end: compilations_static_2"

  end subroutine compilations_static_2
```

22.7 Integration

This module manages phase space setup, matrix-element evaluation and integration, as far as it is not done by lower-level routines, in particular in the `processes` module.

⟨integrations.f90⟩≡
  ⟨*File header*⟩

```
  module integrations
```

  ⟨*Use kinds*⟩
  ⟨*Use strings*⟩
  ⟨*Use file utils*⟩
```
  use diagnostics !NODEP!
  use unit_tests
  use os_interface
  use cputime
  use sm_qcd
  use ifiles
  use lexers
  use parser
  use flavors
  use pdg_arrays
  use variables
  use expressions
  use models
  use interactions
  use sf_mappings
  use sf_base
  use phs_base
  use mappings
  use phs_forests
  use phs_wood
  use rng_base
  use mci_base
  use process_libraries
  use prc_core
  use processes
  use process_stacks
  use iterations
  use rt_data
  use dispatch
  use process_configurations
  use compilations
```

⟨*Standard module head*⟩

⟨*Integrations: public*⟩

⟨*Integrations: types*⟩

```
contains
```

⟨*Integrations: procedures*⟩

⟨*Integrations: tests*⟩

```
end module integrations
```

22.7.1   The integration type

This type holds all relevant data, the integration methods operates on this. In contrast to the `simulation_t` introduced later, the `integration_t` applies to a single process.

⟨*Integrations: public*⟩≡
```
    public :: integration_t
```

⟨*Integrations: types*⟩≡
```
    type :: integration_t
      private
      type(string_t) :: process_id
      type(string_t) :: run_id
      type(process_t), pointer :: process => null ()
      logical :: rebuild_phs = .false.
      logical :: ignore_phs_mismatch = .false.
      logical :: phs_only = .false.
      logical :: process_has_me = .true.
      integer :: n_calls_test = 0
      logical :: vis_history = .true.
      type(string_t) :: history_filename
      type(string_t) :: log_filename
     contains
     ⟨Integrations: integration: TBP⟩
    end type integration_t
```

22.7.2   Initialization

Initialization, first part: Create and initialize a process entry and push it on the stack. Only the basic process data (ID, run ID, etc.) are configured, we postpone the rest.

⟨*Integrations: integration: TBP*⟩≡
```
    procedure :: create_process => integration_create_process
```

⟨*Integrations: procedures*⟩≡
```
    subroutine integration_create_process (intg, process_id, global) !, verbose)
      class(integration_t), intent(out) :: intg
```

```
      type(rt_data_t), intent(inout), target :: global
      type(string_t), intent(in) :: process_id
      type(var_list_t), pointer :: var_list
      type(qcd_t) :: qcd
      class(rng_factory_t), allocatable :: rng_factory
      type(process_entry_t), pointer :: process_entry

      var_list => global%var_list
      intg%process_id = process_id
      intg%run_id = var_list_get_sval (var_list, var_str ("$run_id"))

      call dispatch_qcd (qcd, global)
      call dispatch_rng_factory (rng_factory, global)

      allocate (process_entry)
      call process_entry%init (intg%process_id, intg%run_id, global%prclib, &
           global%os_data, qcd, rng_factory, global%model_list)
      call global%process_stack%push (process_entry)

    end subroutine integration_create_process
```

Complete process configuration.

   If the `process` argument is given, use it. Otherwise, take the process object from the stack.

⟨*Integrations: integration: TBP*⟩+≡
```
    procedure :: setup_process => integration_setup_process
```

⟨*Integrations: procedures*⟩+≡
```
    subroutine integration_setup_process (intg, global, process, verbose)
      class(integration_t), intent(inout) :: intg
      type(rt_data_t), intent(inout), target :: global
      type(process_t), intent(in), target, optional :: process
      logical, intent(in), optional :: verbose

22.7.3 Integration

Integrate: do the final integration. Here, we do a multi-iteration integration. Again, we skip iterations that are already on file. Record the results in the global variable list.

⟨*Integrations: integration: TBP*⟩+≡
```
procedure :: evaluate => integration_evaluate
```

⟨*Integrations: procedures*⟩+≡
```
subroutine integration_evaluate &
     (intg, process_instance, i_mci, pass, it_list, pacify)
  class(integration_t), intent(inout) :: intg
  type(process_instance_t), intent(inout), target :: process_instance
  integer, intent(in) :: i_mci
  integer, intent(in) :: pass
  type(iterations_list_t), intent(in) :: it_list
  logical, intent(in), optional :: pacify
  integer :: n_calls, n_it
  logical :: adapt_grids, adapt_weights, final

  n_it = it_list%get_n_it (pass)
  n_calls = it_list%get_n_calls (pass)
  adapt_grids = it_list%adapt_grids (pass)
  adapt_weights = it_list%adapt_weights (pass)
  final = pass == it_list%get_n_pass ()

  call intg%process%integrate (process_instance, &
       i_mci, n_it, n_calls, adapt_grids, adapt_weights, &
       final, pacify)

end subroutine integration_evaluate
```

In case the user has not provided a list of iterations, make a reasonable default. This can depend on the process. The usual approach is to define two distinct passes, one for adaptation and one for integration.

⟨*Integrations: integration: TBP*⟩+≡
```
    procedure :: make_iterations_list => integration_make_iterations_list
```

⟨*Integrations: procedures*⟩+≡
```
    subroutine integration_make_iterations_list (intg, it_list)
      class(integration_t), intent(in) :: intg
      type(iterations_list_t), intent(out) :: it_list
      integer :: pass, n_pass
      integer, dimension(:), allocatable :: n_it, n_calls
      logical, dimension(:), allocatable :: adapt_grids, adapt_weights
      n_pass = intg%process%get_n_pass_default ()
      allocate (n_it (n_pass), n_calls (n_pass))
      allocate (adapt_grids (n_pass), adapt_weights (n_pass))
      do pass = 1, n_pass
         n_it(pass)           = intg%process%get_n_it_default (pass)
         n_calls(pass)        = intg%process%get_n_calls_default (pass)
         adapt_grids(pass)    = intg%process%adapt_grids_default (pass)
         adapt_weights(pass) = intg%process%adapt_weights_default (pass)
      end do
      call it_list%init (n_it, n_calls, &
           adapt_grids = adapt_grids, adapt_weights = adapt_weights)
    end subroutine integration_make_iterations_list
```

22.7.4 API for integration objects

This initializer does everything except assigning cuts/scale/weight expressions. If ok is false, initialization failed, and the integration should be skipped.

If me_only is set, prepare just matrix-element evaluation: no phase space, no iterations.

⟨*Integrations: integration: TBP*⟩+≡
```
    procedure :: init => integration_init
```

⟨*Integrations: procedures*⟩+≡
```
    subroutine integration_init (intg, process_id, global)
      class(integration_t), intent(out) :: intg
      type(string_t), intent(in) :: process_id
      type(rt_data_t), intent(inout), target :: global

      call intg%create_process (process_id, global)
      call intg%setup_process (global)
    end subroutine integration_init
```

Do the integration for a single process, both warmup and final evaluation. The eff_reset flag is to suppress numerical noise in the graphical output of the integration history.

⟨*Integrations: integration: TBP*⟩+≡
```
    procedure :: integrate => integration_integrate
```

⟨*Integrations: procedures*⟩+≡

```
subroutine integration_integrate (intg, global, eff_reset)
  class(integration_t), intent(inout) :: intg

        call msg_message ()
     end if
     call process_instance%final ()
   end subroutine integration_sampler_test
```

Simply integrate, do a dummy integration if necessary. The `integration` object exists only internally.

The `init_only` flag can be used to skip the actual integration part. We will end up with a process object that is completely initialized, including phase space configuration.

The `eff_reset` flag is to suppress numerical noise in the visualization of the integration history.

⟨*Integrations: public*⟩+≡
```
    public :: integrate_process

```

⟨*Integrations: public*⟩+≡
```
    public :: integrations_history_test
```

⟨*Integrations: tests*⟩+≡
```
    subroutine integrations_history_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
    ⟨Integrations: execute history tests⟩
      end subroutine integrations_history_test
```

Integration of test process

Compile and integrate an intrinsic test matrix element (`prc_test` type). The phase-space implementation is `phs_single` (single-particle phase space), the integrator is `mci_midpoint`.

The cross section for the $2 \rightarrow 2$ process $ss \rightarrow ss$ with its constant matrix element is given by

$$\sigma = c \times f \times \Phi_2 \times |M|^2. \tag{22.1}$$

c is the conversion constant

$$c = 0.3894 \times 10^{12} \text{ fb GeV}^2. \tag{22.2}$$

f is the flux of the incoming particles with mass $m = 125\,\text{GeV}$ and energy $\sqrt{s} = 1000\,\text{GeV}$

$$f = \frac{(2\pi)^4}{2\lambda^{1/2}(s, m^2, m^2)} = \frac{(2\pi)^4}{2\sqrt{s}\,\sqrt{s - 4m^2}} = 8.048 \times 10^{-4} \text{ GeV}^{-2} \tag{22.3}$$

Φ_2 is the volume of the two-particle phase space

$$\Phi_2 = \frac{1}{4(2\pi)^5} = 2.5529 \times 10^{-5}. \tag{22.4}$$

The squared matrix element $|M|^2$ is unity. Combining everything, we obtain

$$\sigma = 8000 \text{ fb} \tag{22.5}$$

This number should appear as the final result.

Note: In this and the following test, we reset the Fortran compiler and flag variables immediately before they are printed, so the test is portable.

Structure functions

Compile and integrate an intrinsic test matrix element (`prc_test` type) using
the default (`phs_wood`) phase-space implementation. The integration method is
`vamp`. There is a structure function of type `unit_test`.

   We use a test structure function $f(x) = x$ for both beams. Together with the
$1/x_1 x_2$ factor from the phase-space flux and a unit matrix element, we should
get the same result as previously for the process without structure functions.
There is a slight correction due to the m_s mass which we set to zero here.

⟨*Integrations: execute tests*⟩+≡

22.8   Event Streams

This module manages I/O from/to multiple concurrent event streams. Usually, there is at most one input stream, but several output streams. For the latter, we set up an array which can hold `eio_t` (event I/O) objects of different dynamic types simultaneously. One of them may be marked as an input channel.

⟨event_streams.f90⟩≡
  ⟨*File header*⟩

  module event_streams

  ⟨*Use kinds*⟩

    use eio_base
    use rt_data
    use dispatch

  ⟨*Standard module head*⟩

  ⟨*Event streams: public*⟩

  ⟨*Event streams: types*⟩

  contains

  ⟨*Event streams: tests*⟩

  ⟨*Event streams: procedures*⟩

  end module event_streams

22.8.1   Event Stream Array

Each entry is an `eio_t` object. Since the type is dynamic, we need a wrapper:

⟨*Event streams: types*⟩≡
```
    type :: event_stream_entry_t
       class(eio_t), allocatable :: eio
    end type event_stream_entry_t
```

An array of event-stream entry objects. If one of the entries is an input channel, `i_in` is the corresponding index.

⟨*Event streams: public*⟩≡
```
    public :: event_stream_array_t
```

⟨*Event streams: types*⟩+≡
```
    type :: event_stream_array_t
       type(event_stream_entry_t), dimension(:), allocatable :: entry
       integer :: i_in = 0
     contains
     ⟨Event streams: event stream array: TBP⟩
    end type event_stream_array_t
```

2929

Output.

⟨*Event streams: event stream array: TBP*⟩≡
```
    procedure :: write => event_stream_array_write
```

⟨*Event streams: procedures*⟩≡
```
    subroutine event_stream_array_write (object, unit)
      class(event_stream_array_t), intent(in) :: object
      integer, intent(in), optional :: unit
      integer :: u, i
      u = output_unit (unit)
      write (u, "(1x,A)")  "Event stream array:"
      if (allocated (object%entry)) then
         select case (size (object%entry))
         case (0)
            write (u, "(3x,A)")  "[empty]"
         case default
            do i = 1, size (object%entry)
               if (i == object%i_in)  write (u, "(1x,A)")  "Input stream:"
               call object%entry(i)%eio%write (u)
            end do
         end select
      else
         write (u, "(3x,A)")  "[undefined]"
      end if
    end subroutine event_stream_array_write
```

Finalize all streams.

⟨*Event streams: event stream array: TBP*⟩+≡
```
    procedure :: final => event_stream_array_final
```

⟨*Event streams: procedures*⟩+≡
```
    subroutine event_stream_array_final (es_array)
      class(event_stream_array_t), intent(inout) :: es_array
      integer :: i
      do i = 1, size (es_array%entry)
         call es_array%entry(i)%eio%final ()
      end do
    end subroutine event_stream_array_final
```

Initialization. We use a generic `sample` name, open event I/O objects for all provided stream types (using the `dispatch_eio` routine), and initialize for the given list of process pointers. If there is an `input` argument, this channel is initialized as an input channel and appended to the array.

The `input_data` or, if not present, `data` may be modified. This happens if we open a stream for reading and get new information there.

⟨*Event streams: event stream array: TBP*⟩+≡
```
    procedure :: init => event_stream_array_init
```

⟨*Event streams: procedures*⟩+≡
```
    subroutine event_stream_array_init &

      do i = 1, size (stream_fmt)
         call dispatch_eio (es_array%entry(i)%eio, stream_fmt(i), global)
         call es_array%entry(i)%eio%init_out (sample, process_ptr, data)
      end do
   end subroutine event_stream_array_init
```

Switch the (only) input channel to an output channel, so further events are appended to the respective stream.

⟨Event streams: event stream array: TBP⟩+≡
```
      procedure :: switch_inout => event_stream_array_switch_inout
```

⟨Event streams: procedures⟩+≡
```
   subroutine event_stream_array_switch_inout (es_array)
     class(event_stream_array_t), intent(inout) :: es_array
     integer :: n
     if (es_array%has_input ()) then
        n = es_array%i_in
        call es_array%entry(n)%eio%switch_inout ()
        es_array%i_in = 0
     else
        call msg_bug ("Reading events: switch_inout: no input stream selected")
     end if
   end subroutine event_stream_array_switch_inout
```

Output an event (with given process number) to all output streams. If there is no output stream, do nothing.

⟨Event streams: event stream array: TBP⟩+≡
```
      procedure :: output => event_stream_array_output
```

⟨Event streams: procedures⟩+≡
```
   subroutine event_stream_array_output (es_array, event, i_prc, event_index)
     class(event_stream_array_t), intent(inout) :: es_array
     type(event_t), intent(in), target :: event
     integer, intent(in) :: i_prc, event_index
     integer :: i
     do i = 1, size (es_array%entry)
        if (i /= es_array%i_in) then
           associate (eio => es_array%entry(i)%eio)
             if (eio%split) then
```

```
                  if (event_index > 1 .and. &
                      mod (event_index, eio%split_n_evt) == 1) then
                    call eio%split_out ()
                  end if
               end if
               call eio%output (event, i_prc, reading = es_array%i_in /= 0)
            end associate
         end if
      end do
   end subroutine event_stream_array_output
```

Input the `i_prc` index which selects the process for the current event. This is separated from reading the event, because it determines which event record to read. `iostat` may indicate an error or an EOF condition, as usual.

⟨*Event streams: event stream array: TBP*⟩+≡
```
    procedure :: input_i_prc => event_stream_array_input_i_prc
```

⟨*Event streams: procedures*⟩+≡
```
    subroutine event_stream_array_input_i_prc (es_array, i_prc, iostat)
      class(event_stream_array_t), intent(inout) :: es_array
      integer, intent(out) :: i_prc
      integer, intent(out) :: iostat
      integer :: n
      if (es_array%has_input ()) then
         n = es_array%i_in
         call es_array%entry(n)%eio%input_i_prc (i_prc, iostat)
      else
         call msg_fatal ("Reading events: no input stream selected")
      end if
    end subroutine event_stream_array_input_i_prc
```

Input an event from the selected input stream. `iostat` may indicate an error or an EOF condition, as usual.

⟨*Event streams: event stream array: TBP*⟩+≡
```
    procedure :: input_event => event_stream_array_input_event
```

⟨*Event streams: procedures*⟩+≡
```
    subroutine event_stream_array_input_event (es_array, event, iostat)
      class(event_stream_array_t), intent(inout) :: es_array
      type(event_t), intent(inout), target :: event
      integer, intent(out) :: iostat
      integer :: n
      if (es_array%has_input ()) then
         n = es_array%i_in
         call es_array%entry(n)%eio%input_event (event, iostat)
      else
         call msg_fatal ("Reading events: no input stream selected")
      end if
    end subroutine event_stream_array_input_event
```

Return true if there is an input channel among the event streams.

⟨*Event streams: event stream array: TBP*⟩+≡
```
    procedure :: has_input => event_stream_array_has_input
```

⟨*Event streams: procedures*⟩+≡
```
function event_stream_array_has_input (es_array) result (flag)
  class(event_stream_array_t), intent(in) :: es_array
  logical :: flag
  flag = es_array%i_in /= 0
end function event_stream_array_has_input
```

22.8.2   Unit Tests

⟨*Event streams: public*⟩+≡
```
public :: event_streams_test
```

⟨*Event streams: tests*⟩≡
```
subroutine event_streams_test (u, results)
  integer, intent(in) :: u
  type(test_results_t), intent(inout) :: results
```
⟨*Event streams: execute tests*⟩
```
end subroutine event_streams_test
```

Empty event stream

This should set up an empty event output stream array, including initialization,
output, and finalization (which are all no-ops).

⟨*Event streams: execute tests*⟩≡
```
call test (event_streams_1, "event_streams_1", &
     "empty event stream array", &
     u, results)
```

⟨*Event streams: tests*⟩+≡
```
subroutine event_streams_1 (u)
  integer, intent(in) :: u
  type(event_stream_array_t) :: es_array
  type(rt_data_t) :: global
  type(event_t) :: event
  type(string_t) :: sample
  type(string_t), dimension(0) :: empty_string_array
  type(process_ptr_t), dimension(0) :: empty_process_ptr_array

  write (u, "(A)")  "* Test output: event_streams_1"
  write (u, "(A)")  "*   Purpose: handle empty event stream array"
  write (u, "(A)")

  sample = "event_streams_1"

  call es_array%init &
       (sample, empty_string_array, empty_process_ptr_array, global)
  call es_array%output (event, 42, 1)
  call es_array%write (u)
  call es_array%final ()

  write (u, "(A)")
  write (u, "(A)")  "* Test output end: event_streams_1"
```

```
      end subroutine event_streams_1
```

Nontrivial event stream

Here we generate a trivial event and choose `raw` output as an entry in the stream
array.

⟨*Event streams: execute tests*⟩+≡
```
      call test (event_streams_2, "event_streams_2", &
           "nontrivial event stream array", &
           u, results)
```

⟨*Event streams: tests*⟩+≡
```
      subroutine event_streams_2 (u)
        integer, intent(in) :: u

         object%has_integral = .true.
      end if
    end subroutine mci_set_init
```

22.9.3 Process-core Safe

This is an object that temporarily holds a process core object. We need this while rescanning a process with modified parameters. After the rescan, we want to restore the original state.

⟨*Simulations: types*⟩+≡
```
type :: core_safe_t
   class(prc_core_t), allocatable :: core
end type core_safe_t
```

22.9.4 Process Object

The simulation works on process objects. This subroutine makes a process object available for simulation. The process is in the process stack. If integration is not yet done, do it.

⟨*Simulations: procedures*⟩+≡
```
subroutine prepare_process (process, process_id, integrate, global)
  type(process_t), pointer, intent(out) :: process
  type(string_t), intent(in) :: process_id
  logical, intent(in) :: integrate
  type(rt_data_t), intent(inout), target :: global
  process => global%process_stack%get_process_ptr (process_id)
  if (.not. associated (process)) then
     if (integrate) then
        call msg_message ("Simulate: process '" &
             // char (process_id) // "' needs integration")
     else
        call msg_message ("Simulate: process '" &
             // char (process_id) // "' needs initialization")
     end if
     call integrate_process (process_id, global, init_only = .not. integrate)
     if (signal_is_pending ())  return
     process => global%process_stack%get_process_ptr (process_id)
     if (associated (process)) then
        if (integrate) then
           call msg_message ("Simulate: integration done")
           call global%process_stack%fill_result_vars (process_id)
        else
           call msg_message ("Simulate: process initialization done")
        end if
     else
        call msg_fatal ("Simulate: process '" &
             // char (process_id) // "' could not be initialized: aborting")
     end if
  end if
end subroutine prepare_process
```

22.9.5 Simulation entry

For each process that we consider for event generation, we need a separate entry. The entry separately records the process ID and run ID. The `weight_mci` array

is used for selecting a component set (which shares a MCI record inside the process container) when generating an event for the current process.

The simulation entry is an extension of the `event_t` event record. This core object contains configuration data, pointers to the process and process instance, the expressions, flags and values that are evaluated at runtime, and the resulting particle set.

The entry explicitly allocate the `process_instance`, which becomes the process-specific workspace for the event record.

If entries with differing environments are present simultaneously, we may need to switch QCD parameters and/or the model event by event. In this case, the `qcd` and/or `model` components are present.

⟨*Simulations: types*⟩+≡
```
type, extends (event_t) :: entry_t
   private
   type(string_t) :: process_id
   type(string_t) :: library
   type(string_t) :: run_id
   logical :: has_integral = .false.
   real(default) :: integral = 0
   real(default) :: error = 0
   real(default) :: process_weight = 0
   logical :: valid = .false.
   type(counter_t) :: counter
   integer :: n_in = 0
   integer :: n_mci = 0
   type(mci_set_t), dimension(:), allocatable :: mci_set
   type(selector_t) :: mci_selector
   type(core_safe_t), dimension(:), allocatable :: core_safe
   type(model_t), pointer :: model => null ()
   type(qcd_t) :: qcd
 contains
 ⟨Simulations: entry: TBP⟩
end type entry_t
```

Output. Write just the configuration, the event is written by a separate routine.

The `verbose` option is unused, it is required by the interface of the base-object method.

⟨*Simulations: entry: TBP*⟩≡
```
procedure :: write_config => entry_write_config
```

⟨*Simulations: procedures*⟩+≡
```
subroutine entry_write_config (object, unit)
  class(entry_t), intent(in) :: object
  integer, intent(in), optional :: unit
  integer :: u, i
  u = output_unit (unit)
  write (u, "(3x,A,A,A)") "Process  = '", char (object%process_id), "'"
  write (u, "(3x,A,A,A)") "Library  = '", char (object%library), "'"
  write (u, "(3x,A,A,A)") "Run      = '", char (object%run_id), "'"
  write (u, "(3x,A,L1)")  "is valid = ", object%valid
  if (object%has_integral) then
     write (u, "(3x,A," // FMT_19 // ")") "Integral = ", object%integral
     write (u, "(3x,A," // FMT_19 // ")") "Error    = ", object%error
```

```
      write (u, "(3x,A,F13.10)")  "Weight     =", object%process_weight
   else
      write (u, "(3x,A)")  "Integral  = [undefined]"
   end if
   write (u, "(3x,A,I0)")   "MCI sets  = ", object%n_mci
   call object%counter%write (u)
   do i = 1, size (object%mci_set)
      write (u, "(A)")
      write (u, "(1x,A,I0,A)")  "MCI set #", i, ":"
      call object%mci_set(i)%write (u)
   end do
   if (allocated (object%core_safe)) then
      do i = 1, size (object%core_safe)
         write (u, "(1x,A,I0,A)")  "Saved process-component core #", i, ":"
         call object%core_safe(i)%core%write (u)
      end do
   end if
end subroutine entry_write_config
```

Finalizer. The `instance` pointer component of the `event_t` base type points to a target which we did explicitly allocate in the `entry_init` procedure. Therefore, we finalize and explicitly deallocate it here. Then we call the finalizer of the base type.

⟨*Simulations: entry: TBP*⟩+≡
```
   procedure :: final => entry_final
```

⟨*Simulations: procedures*⟩+≡
```
   subroutine entry_final (object)
     class(entry_t), intent(inout) :: object
     integer :: i
     if (associated (object%instance)) then
        do i = 1, object%n_mci
           call object%instance%final_simulation (i)
        end do
        call object%instance%final ()
        deallocate (object%instance)
     end if
     call object%event_t%final ()
   end subroutine entry_final
```

Initialization. Search for a process entry and allocate a process instance as an anonymous object, temporarily accessible via the `process_instance` pointer. Assign data by looking at the process object and at the environment.

If `n_alt` is set, we prepare for additional alternate sqme and weight entries.

If the process object is not found initially: if `integrate` is set, attempt an integration pass and try again. Otherwise, just initialize the object.

If `generate` is set, prepare the MCI objects for generating new events. For pure rescanning, this is not necessary.

When done, we assign the `instance` and `process` pointers of the base type by the `connect` method, so we can reference them later.

⟨*Simulations: entry: TBP*⟩+≡
```
   procedure :: init => entry_init

22.9.6 Entries for alternative environment

Entries for alternate environments. [No additional components anymore, so somewhat redundant.]

⟨*Simulations: types*⟩+≡
```
    type, extends (entry_t) :: alt_entry_t
     contains
     ⟨Simulations: alt entry: TBP⟩
    end type alt_entry_t
```

The alternative entries are there to re-evaluate the event, given momenta, in a different context.

Therefore, we allocate a local process object and use this as the reference for the local process instance, when initializing the entry. We temporarily import the `process` object into an `integration_t` wrapper, to take advantage of the associated methods. The local process object is built in the context of the current environment, here called `global`. Then, we initialize the process instance.

The `master_process` object contains the integration results to which we refer when recalculating an event. Therefore, we use this object instead of the locally built `process` when we extract the integration results.

The locally built `process` object should be finalized when done. It remains accessible via the `event_t` base object of `entry`, which contains pointers to the process and instance.

⟨*Simulations: alt entry: TBP*⟩≡
```
    procedure :: init_alt => alt_entry_init
```

⟨*Simulations: procedures*⟩+≡

```

22.9.7 The simulation type

Each simulation object corresponds to an event sample, identified by the `sample_id`.
    The simulation may cover several processes simultaneously. All process-
specific data, including the event records, are stored in the `entry` subobjects.

The `current` index indicates which record was selected last. `version` is foreseen to contain a tag on the `WHIZARD` event file version. It can be

⟨*Simulations: public*⟩≡
```
    public :: simulation_t
```

⟨*Simulations: types*⟩+≡
```
    type :: simulation_t
       private
       type(string_t) :: sample_id
       logical :: unweighted = .true.
       logical :: negative_weights = .false.
       integer :: norm_mode = NORM_UNDEFINED
       logical :: pacify = .false.
       integer :: n_max_tries = 10000
       integer :: n_prc = 0
       integer :: n_alt = 0
       logical :: has_integral = .false.
       logical :: valid

```

Initialization. We can deduce all data from the given list of process IDs and the global data set. The process objects are taken from the stack. Once the individual integrals are known, we add them (and the errors), to get the sample integral.

  If there are alternative environments, we suspend initialization for setting up alternative process objects, then restore the master process and its parameters. The generator or rescanner can then switch rapidly between processes.

If `integrate` is set, we make sure that all affected processes are integrated before simulation. This is necessary if we want to actually generate events. If `integrate` is unset, we don't need the integral because we just rescan existing events. In that case, we just need compiled matrix elements.

If `generate` is set, we prepare for actually generating events. Otherwise, we may only read and rescan events.

The number of events that we want to simulate is determined by the settings
of `n_events`, `luminosity`, and `?unweighted`. For weighted events, we take
`n_events` at face value as the number of matrix element calls. For unweighted
events, if the process is a decay, `n_events` is the number of unweighted events.
In these cases, the luminosity setting is ignored.

For unweighted events with a scattering process, we calculate the event num-
ber that corresponds to the luminosity, given the current value of the integral.
We then compare this with `n_events` and choose the larger number.

Compute the checksum of the process set. We retrieve the MD5 sums of all processes. This depends only on the process definitions, while parameters are not considered. The configuration checksum is retrieved from the MCI records in the process objects and furthermore includes beams, parameters, integration results, etc., so matching the latter should guarantee identical physics.

Generate a predefined number of events. First select a process and a component set, then generate an event for that process and factorize the quantum state. The pair of random numbers can be used for factorization.

When generating events, we drop all configurations where the event is marked as incomplete. This happens if the event fails cuts. In fact, such events are dropped already by the sampler if unweighting is in effect, so this can happen only for weighted events. By setting a limit given by `sample_max_tries` (user parameter), we can avoid an endless loop.

Compute the event matrix element and weight for all alternative environments, given the current event and selected process. We first copy the particle set, then temporarily update the process core with local parameters, recalculate everything, and restore the process core.

The event weight is obtained by rescaling the original event weight with the ratio of the new and old `sqme` values. (In particular, if the old value was zero, the weight will stay zero.)

Note: this may turn out to be inefficient because we always replace all parameters and recalculate everything, once for each event and environment. However, a more fine-grained control requires more code. In any case, while we may keep multiple process cores (which stay constant for a simulation run), we still have to update the external matrix element parameters event by event. The matrix element "object" is present only once.

Rescan an undefined number of events.

If `update_event` or `update_sqme` is set, we have to recalculate the event, starting from the particle set. If the latter is set, this includes the squared matrix element (i.e., the amplitude is evaluated). Otherwise, only kinematics and observables derived from it are recovered.

If any of the update flags is set, we will come up with separate `sqme_prc` and `weight_prc` values. (The latter is only distinct if `update_weight` is set.) Otherwise, we accept the reference values.

      end if
    end subroutine simulation_rescan
```

These routines take care of temporary parameter redefinitions that we want to
take effect while recalculating the matrix elements. We extract the core(s) of
the processes that we are simulating, apply the changes, and make sure that the
changes are actually used. This is the duty of `dispatch_core_update`. When
done, we restore the original versions using `dispatch_core_restore`.

⟨*Simulations: simulation: TBP*⟩+≡
```
    procedure :: update_processes => simulation_update_processes
    procedure :: restore_processes => simulation_restore_processes
```

⟨*Simulations: procedures*⟩+≡
```
    subroutine simulation_update_processes (simulation, &
        model, qcd, helicity_selection)
      class(simulation_t), intent(inout) :: simulation
      type(model_t), intent(in), optional, target :: model
      type(qcd_t), intent(in), optional :: qcd

        call simulation%entry(i)%restore_process ()
      end do
    end subroutine simulation_restore_processes
```

22.9.8   Event Stream I/O

Write an event to a generic `eio` event stream. The process index must be selected, or the current index must be available.

⟨*Simulations: simulation: TBP*⟩+≡
```
    generic :: write_event => write_event_eio
    procedure :: write_event_eio => simulation_write_event_eio
```

⟨*Simulations: procedures*⟩+≡
```
    subroutine simulation_write_event_eio (object, eio, i_prc)
      class(simulation_t), intent(in) :: object
      class(eio_t), intent(inout) :: eio
      integer, intent(in), optional :: i_prc
      integer :: current
      if (present (i_prc)) then
         current = i_prc
      else
         current = object%i_prc
      end if
      if (current > 0) then
         if (object%split_n_evt > 0) then
            if (object%counter%total > 1 .and. &
                 mod (object%counter%total, object%split_n_evt) == 1) then
               call eio%split_out ()
            end if
         end if
         call eio%output (object%entry(current)%event_t, current)
      else
         call msg_fatal ("Simulation: write event: no process selected")
      end if
    end subroutine simulation_write_event_eio
```

Read an event from a generic `eio` event stream. The event stream element must specify the process within the sample (`i_prc`), the MC group for this process (`i_mci`), the selected term (`i_term`), the selected MC integration `channel`, and the particle set of the event.

   We may encounter EOF, which we indicate by storing 0 for the process index `i_prc`. An I/O error will be reported, and we also abort reading.

⟨*Simulations: simulation: TBP*⟩+≡

```
      generic :: read_event => read_event_eio
      procedure :: read_event_eio => simulation_read_event_eio
```

⟨*Simulations: procedures*⟩+≡
```
      subroutine simulation_read_event_eio (object, eio)
        class(simulation_t), intent(inout) :: object
        class(eio_t), intent(inout) :: eio
        integer :: iostat, current
        call eio%input_i_prc (current, iostat)
        select case (iostat)
        case (0)
           object%i_prc = current
           call eio%input_event (object%entry(current)%event_t, iostat)
        end select
        select case (iostat)
        case (:-1)
           object%i_prc = 0
           object%i_mci = 0
        case (1:)
           call msg_error ("Reading events: I/O error, aborting read")
           object%i_prc = 0
           object%i_mci = 0
        case default
           object%i_mci = object%entry(current)%get_i_mci ()
        end select
      end subroutine simulation_read_event_eio
```

22.9.9   Event Stream Array

Write an event using an array of event I/O streams. The process index must be selected, or the current index must be available.

⟨*Simulations: simulation: TBP*⟩+≡
```
      generic :: write_event => write_event_es_array
      procedure :: write_event_es_array => simulation_write_event_es_array
```

⟨*Simulations: procedures*⟩+≡
```
      subroutine simulation_write_event_es_array (object, es_array)
        class(simulation_t), intent(in) :: object
        class(event_stream_array_t), intent(inout) :: es_array
        integer :: i_prc, event_index
        i_prc = object%i_prc
        if (i_prc > 0) then
           event_index = object%counter%total
           call es_array%output (object%entry(i_prc)%event_t, i_prc, event_index)
        else
           call msg_fatal ("Simulation: write event: no process selected")
        end if
      end subroutine simulation_write_event_es_array
```

Read an event using an array of event I/O streams. Reading is successful if there is an input stream within the array, and if a valid event can be read from that stream. If there is a stream, but EOF is passed when reading the first

item, we switch the channel to output and return failure but no error message, such that new events can be appended to that stream.

⟨*Simulations: simulation: TBP*⟩+≡
```
    generic :: read_event => read_event_es_array
    procedure :: read_event_es_array => simulation_read_event_es_array
```

⟨*Simulations: procedures*⟩+≡
```
    subroutine simulation_read_event_es_array (object, es_array, enable_switch, &
        fail)
      class(simulation_t), intent(inout) :: object
      class(event_stream_array_t), intent(inout) :: es_array
      logical, intent(in) :: enable_switch
      logical, intent(out) :: fail
      integer :: iostat, i_prc
      if (es_array%has_input ()) then
          fail = .false.
          call es_array%input_i_prc (i_prc, iostat)
          select case (iostat)
          case (0)
             object%i_prc = i_prc
             call es_array%input_event (object%entry(i_prc)%event_t, iostat)
          case (:-1)
             write (msg_buffer, "(A,1x,I0,1x,A)")  &
                   "... event file terminates after", &
                   object%counter%read, "events."

          case default
             write (msg_buffer, "(A,1x,I0,1x,A)")  &
                   "Reading events: I/O error, aborting read after", &
                   object%counter%read, "events."
             call msg_error ()
             object%i_prc = 0
             object%i_mci = 0
             fail = .true.
          end select
      else
          fail = .true.
      end if
    end subroutine simulation_read_event_es_array
```

22.9.10 Recover event

Recalculate the process instance contents, given an event with known particle set. The indices for MC, term, and channel must be already set. The `recalculate` method of the selected entry will import the result into `sqme_prc` and `weight_prc`.

⟨*Simulations: simulation: TBP*⟩+≡
```
procedure :: recalculate => simulation_recalculate
```

⟨*Simulations: procedures*⟩+≡
```
subroutine simulation_recalculate (simulation, update_sqme, update_weight, &
    recover_beams)
  class(simulation_t), intent(inout) :: simulation
  logical, intent(in) :: update_sqme, update_weight
  logical, intent(in), optional :: recover_beams
  integer :: i_prc
  i_prc = simulation%i_prc
  associate (entry => simulation%entry(i_prc))
    if (update_weight) then
      call simulation%entry(i_prc)%recalculate &
           (update_sqme = update_sqme, recover_beams = recover_beams, &
           weight_factor = entry%get_kinematical_weight ())
    else
      call simulation%entry(i_prc)%recalculate &
           (update_sqme = update_sqme, recover_beams = recover_beams)
    end if
  end associate
end subroutine simulation_recalculate
```

22.9.11 Extract contents

Return an array of pointers to the currently selected processes.

⟨*Simulations: simulation: TBP*⟩+≡
```
procedure :: get_process_ptr => simulation_get_process_ptr
```

⟨*Simulations: procedures*⟩+≡
```
function simulation_get_process_ptr (simulation) result (ptr)
  class(simulation_t), intent(in) :: simulation
  type(process_ptr_t), dimension(:), allocatable :: ptr
  integer :: i
  allocate (ptr (simulation%n_prc))
  do i = 1, size (ptr)
     ptr(i)%ptr => simulation%entry(i)%get_process_ptr ()
  end do
end function simulation_get_process_ptr
```

Return the MD5 sum that summarizes configuration and integration (but not the event file). Used for initializing the event streams.

⟨*Simulations: simulation: TBP*⟩+≡
```
procedure :: get_md5sum_prc => simulation_get_md5sum_prc
procedure :: get_md5sum_cfg => simulation_get_md5sum_cfg
procedure :: get_md5sum_alt => simulation_get_md5sum_alt
```

⟨*Simulations: procedures*⟩+≡

```
function simulation_get_md5sum_prc (simulation) result (md5sum)
  class(simulation_t), intent(in) :: simulation
  character(32) :: md5sum
  md5sum = simulation%md5sum_prc
end function simulation_get_md5sum_prc

function simulation_get_md5sum_cfg (simulation) result (md5sum)
  class(simulation_t), intent(in) :: simulation
  character(32) :: md5sum
  md5sum = simulation%md5sum_cfg
end function simulation_get_md5sum_cfg

function simulation_get_md5sum_alt (simulation, i) result (md5sum)
  class(simulation_t), intent(in) :: simulation
  integer, intent(in) :: i
  character(32) :: md5sum
  md5sum = simulation%md5sum_alt(i)
end function simulation_get_md5sum_alt
```

Return data that may be useful for writing event files..

⟨*Simulations: simulation: TBP*⟩+≡

```
procedure :: get_data => simulation_get_data
```

⟨*Simulations: procedures*⟩+≡

```
function simulation_get_data (simulation, alt) result (data)
  class(simulation_t), intent(in) :: simulation

23.1.1   The command type

The command type is a generic type that holds any command, compiled for execution.

Each command may come with its own local environment. The command list that determines this environment is allocated as `options`, if necessary. (It has to be allocated as a pointer because the type definition is recursive.) The local environment is available as a pointer which either points to the global environment, or is explicitly allocated and initialized.

⟨*Commands: types*⟩≡
```
    type, abstract :: command_t
      type(parse_node_t), pointer :: pn => null ()
      class(command_t), pointer :: next => null ()
      type(parse_node_t), pointer :: pn_opt => null ()
      type(command_list_t), pointer :: options => null ()
      type(rt_data_t), pointer :: local => null ()
    contains
    ⟨Commands: command: TBP⟩
```

```
        end type command_t
```

Finalizer: If there is an option list, finalize the option list and deallocate. If not, the local environment is just a pointer.

⟨*Commands: command: TBP*⟩≡
```
    procedure :: final => command_final
```

⟨*Commands: procedures*⟩≡
```
    recursive subroutine command_final (cmd)
      class(command_t), intent(inout) :: cmd
      if (associated (cmd%options)) then
         call cmd%options%final ()
         deallocate (cmd%options)
         call cmd%local%local_final ()
         deallocate (cmd%local)
      else
         cmd%local => null ()
      end if
    end subroutine command_final
```

Allocate a command with the appropriate concrete type. Store the parse node pointer in the command object, so we can reference to it when compiling.

⟨*Commands: procedures*⟩+≡
```
    subroutine dispatch_command (command, pn)
      class(command_t), intent(inout), pointer :: command
      type(parse_node_t), intent(in), target :: pn
      select case (char (parse_node_get_rule_key (pn)))
      case ("cmd_model")

      case ("cmd_scan")
         allocate (cmd_scan_t :: command)
      case ("cmd_if")
         allocate (cmd_if_t :: command)
      case ("cmd_include")
         allocate (cmd_include_t :: command)
      case ("cmd_quit")
         allocate (cmd_quit_t :: command)
      case default
         print *, char (parse_node_get_rule_key (pn))
         call msg_bug ("Command not implemented")
      end select
      command%pn => pn
    end subroutine dispatch_command
```

Output. We allow for indentation so we can display a command tree.

⟨*Commands: command: TBP*⟩+≡
```
      procedure (command_write), deferred :: write
```

⟨*Commands: interfaces*⟩≡
```
      abstract interface
        subroutine command_write (cmd, unit, indent)
          import
          class(command_t), intent(in) :: cmd
          integer, intent(in), optional :: unit, indent
        end subroutine command_write
      end interface
```

Compile a command. The command type is already fixed, so this is a deferred type-bound procedure.

⟨*Commands: command: TBP*⟩+≡
```
      procedure (command_compile), deferred :: compile
```

⟨*Commands: interfaces*⟩+≡
```
      abstract interface
        subroutine command_compile (cmd, global)
          import
          class(command_t), intent(inout) :: cmd
          type(rt_data_t), intent(inout), target :: global
        end subroutine command_compile
      end interface
```

Execute a command. This will use and/or modify the runtime data set. If the
`quit` flag is set, the caller should terminate command execution.

⟨*Commands: command: TBP*⟩+≡
```
    procedure (command_execute), deferred :: execute
```

⟨*Commands: interfaces*⟩+≡
```
    abstract interface
       subroutine command_execute (cmd, global)
         import
         class(command_t), intent(inout) :: cmd
         type(rt_data_t), intent(inout), target :: global
       end subroutine command_execute
    end interface
```

23.1.2   Options

The `options` command list is allocated, initialized, and executed, if the com-
mand is associated with an option text in curly braces. If present, a separate
local runtime data set `local` will be allocated and initialized; otherwise, `local`
becomes a pointer to the global dataset.

For output, we indent the options list.

⟨*Commands: command: TBP*⟩+≡
```
    procedure :: write_options => command_write_options
```

⟨*Commands: procedures*⟩+≡
```
    recursive subroutine command_write_options (cmd, unit, indent)
      class(command_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: ind
      ind = 1;  if (present (indent))  ind = indent + 1
      if (associated (cmd%options))  call cmd%options%write (unit, ind)
    end subroutine command_write_options
```

Compile the options list, if any. This implies initialization of the local environ-
ment. Should be done once the `pn_opt` node has been assigned (if applicable),
but before the actual command compilation.

⟨*Commands: command: TBP*⟩+≡
```
    procedure :: compile_options => command_compile_options
```

⟨*Commands: procedures*⟩+≡
```
    recursive subroutine command_compile_options (cmd, global)
      class(command_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      if (associated (cmd%pn_opt)) then
         allocate (cmd%local)
         call cmd%local%local_init (global)
         call global%copy_globals (cmd%local)
         allocate (cmd%options)
         call cmd%options%compile (cmd%pn_opt, cmd%local)
         call global%restore_globals (cmd%local)
      else
         cmd%local => global
```

```
      end if
   end subroutine command_compile_options
```

Execute options. First prepare the local environment, then execute the command list.

⟨*Commands: command: TBP*⟩+≡
```
   procedure :: execute_options => cmd_execute_options
```

⟨*Commands: procedures*⟩+≡
```
   recursive subroutine cmd_execute_options (cmd, global)
     class(command_t), intent(inout) :: cmd
     type(rt_data_t), intent(inout), target :: global
     if (associated (cmd%options)) then
        call cmd%local%link (global)
        call cmd%options%execute (cmd%local)
     end if
   end subroutine cmd_execute_options
```

This must be called after the parent command has been executed, to undo temporary modifications to the global environment.

⟨*Commands: command: TBP*⟩+≡
```
   procedure :: reset_options => cmd_reset_options
```

⟨*Commands: procedures*⟩+≡
```
   subroutine cmd_reset_options (cmd, global)
     class(command_t), intent(inout) :: cmd
     type(rt_data_t), intent(inout), target :: global
     if (associated (cmd%options)) then
        call global%restore (cmd%local)
     end if
   end subroutine cmd_reset_options
```

23.1.3 Specific command types

Model configuration

The command declares a model, looks for the specified file and loads it.

⟨*Commands: types*⟩+≡
```
   type, extends (command_t) :: cmd_model_t
     private
     type(string_t) :: name
    contains
    ⟨Commands: cmd model: TBP⟩
   end type cmd_model_t
```

Output

⟨*Commands: cmd model: TBP*⟩≡
```
   procedure :: write => cmd_model_write
```

⟨*Commands: procedures*⟩+≡

```
subroutine cmd_model_write (cmd, unit, indent)
  class(cmd_model_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = output_unit (unit);  if (u < 0)  return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,'""',A,'""')")  "model =", char (cmd%name)
end subroutine cmd_model_write
```

Compile. Get the model name and read the model from file, so it is readily available when the command list is executed.

⟨*Commands: cmd model: TBP*⟩+≡

```
procedure :: compile => cmd_model_compile
```

⟨*Commands: procedures*⟩+≡

```
subroutine cmd_model_compile (cmd, global)
  class(cmd_model_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_name
  type(string_t) :: filename
  pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
  cmd%name = parse_node_get_string (pn_name)

Library configuration

We configure a process library that should hold the subsequently defined processes. If the referenced library exists already, just make it the currently active one.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_library_t
      private
      type(string_t) :: name
    contains
    ⟨Commands: cmd library: TBP⟩
    end type cmd_library_t
```

Output.

⟨*Commands: cmd library: TBP*⟩≡
```
    procedure :: write => cmd_library_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_library_write (cmd, unit, indent)
      class(cmd_library_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit)
      call write_indent (u, indent)
      write (u, "(1x,A,1x,'""',A,'""')")  "library =", char (cmd%name)
    end subroutine cmd_library_write
```

Compile. Get the library name.

⟨*Commands: cmd library: TBP*⟩+≡
```
    procedure :: compile => cmd_library_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_library_compile (cmd, global)
      class(cmd_library_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_name
      pn_name => parse_node_get_sub_ptr (cmd%pn, 3)
      cmd%name = parse_node_get_string (pn_name)
    end subroutine cmd_library_compile
```

Execute: Initialize a new library and push it on the library stack (if it does not yet exist). Insert a pointer to the library into the global data record. Then, try to load the library unless the `rebuild` flag is set.

⟨*Commands: cmd library: TBP*⟩+≡
```
    procedure :: execute => cmd_library_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_library_execute (cmd, global)
      class(cmd_library_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(prclib_entry_t), pointer :: lib_entry
```

```
      type(process_library_t), pointer :: lib
      logical :: rebuild_library
      lib => global%prclib_stack%get_library_ptr (cmd%name)
      rebuild_library = &
           var_list_get_lval (global%var_list, var_str ("?rebuild_library"))
      if (.not. (associated (lib))) then
         allocate (lib_entry)
         call lib_entry%init (cmd%name)
         lib => lib_entry%process_library_t
         call global%add_prclib (lib_entry)
      else
         call global%update_prclib (lib)
      end if
      if (associated (lib) .and. .not. rebuild_library) then
         call lib%update_status (global%os_data)
      end if
    end subroutine cmd_library_execute
```

Process configuration

We define a process-configuration command as a specific type. The incoming
and outgoing particles are given evaluation-trees which we transform to PDG-
code arrays. For transferring to O'MEGA, they are reconverted to strings.

   For the incoming particles, we store parse nodes individually. We do not yet
resolve the outgoing state, so we store just a single parse node.

   This also includes the choice of method for the corresponding process: omega
for O'MEGA matrix elements, test for special processes generated by WHIZARD,
external for using an external matrix element and dipole for generating dipole
subtraction terms.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_process_t
      private
      type(string_t) :: id
      integer :: n_in  = 0
      type(parse_node_p), dimension(:), allocatable :: pn_pdg_in
      type(parse_node_t), pointer :: pn_out => null ()
    contains
    ⟨Commands: cmd process: TBP⟩
    end type cmd_process_t
```

Output. The particle expressions are not resolved, so we just list the number of
incoming particles.

⟨*Commands: cmd process: TBP*⟩≡
```
    procedure :: write => cmd_process_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_process_write (cmd, unit, indent)
      class(cmd_process_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
```

```
      write (u, "(1x,A,A,A,I0,A)")  "process: ", char (cmd%id), " (", &
           size (cmd%pn_pdg_in), " -> X)"
      call cmd%write_options (u, indent)
   end subroutine cmd_process_write
```

Compile. Find and assign the parse nodes.

⟨*Commands: cmd process: TBP*⟩+≡
```
    procedure :: compile => cmd_process_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_process_compile (cmd, global)
      class(cmd_process_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_id, pn_in, pn_codes
      integer :: i
      pn_id => parse_node_get_sub_ptr (cmd%pn, 2)
      pn_in  => parse_node_get_next_ptr (pn_id, 2)
      cmd%pn_out => parse_node_get_next_ptr (pn_in, 2)
      cmd%pn_opt => parse_node_get_next_ptr (cmd%pn_out)
      call cmd%compile_options (global)
      cmd%id = parse_node_get_string (pn_id)
      cmd%n_in  = parse_node_get_n_sub (pn_in)
      pn_codes => parse_node_get_sub_ptr (pn_in)
      allocate (cmd%pn_pdg_in (cmd%n_in))
      do i = 1, cmd%n_in
         cmd%pn_pdg_in(i)%ptr => pn_codes
         pn_codes => parse_node_get_next_ptr (pn_codes)
      end do
    end subroutine cmd_process_compile
```

Command execution. Evaluate the subevents, transform PDG codes into strings, and add the current process configuration to the process library.

The initial state will be unique (one or two particles). For the final state, we allow for expressions. The expressions will be expanded until we have a sum of final states. Each distinct final state will get its own process component.

To identify equivalent final states, we transform the final state into an array of PDG codes, which we sort and compare. If a particle entry is actually a PDG array, only the first entry in the array is used for the comparison. The user should make sure that there is no overlap between different particles or arrays which would make the expansion ambiguous.

⟨*Commands: cmd process: TBP*⟩+≡
```
    procedure :: execute => cmd_process_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_process_execute (cmd, global)

  end if
end subroutine cmd_compile_compile
```

Command execution. Generate code, write driver, compile and link. Do this for all libraries in the list.

If no library names have been given and stored while compiling this command, we collect all libraries from the current stack and compile those.

We can compile static libraries (which actually just loads them). However, we can't incorporate in a generated executable.

⟨*Commands: cmd compile: TBP*⟩+≡

```
procedure :: execute => cmd_compile_execute
```

3018

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_compile_execute (cmd, global)
      class(cmd_compile_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(string_t), dimension(:), allocatable :: libname, libname_static
      integer :: i
      if (allocated (cmd%libname)) then
         allocate (libname (size (cmd%libname)))
         libname = cmd%libname
      else
         call cmd%local%prclib_stack%get_names (libname)
      end if
      if (cmd%make_executable) then
         call get_prclib_static (libname_static)
         do i = 1, size (libname)
            if (any (libname_static == libname(i))) then
               call msg_fatal ("Compile: can't include static library '" &
                    // char (libname(i)) // "'")
            end if
         end do
         call compile_executable (cmd%exec_name, libname, cmd%local)
      else
         do i = 1, size (libname)

      end subroutine cmd_exec_execute
```

Variable declaration

A variable can have various types. Hold the definition as an eval tree.

There are intrinsic variables, user variables, and model variables. The latter are further divided in independent variables and dependent variables.

Regarding model variables: When dealing with them, we always look at two variable lists in parallel. The global (or local) variable list contains the user-visible values. It includes variables that correspond to variables in the current model's list. These, in turn, are pointers to the model's parameter list, so the model is always in sync, internally. To keep the global variable list in sync with the model, the global variables carry the `is_copy` property and contain a separate pointer to the model variable. (The pointer is reassigned whenever the model changes.) Modifying the global variable changes two values simultaneously: the visible value and the model variable, via this extra pointer. After each modification, we update dependent parameters in the model variable list and re-synchronize the global variable list (again, using these pointers) with the model variable this. In the last step, modifications in the derived parameters become visible.

When we integrate a process, we capture the current variable list of the current model in a separate model instance, which is stored in the process object. Thus, the model parameters associated to this process at this time are preserved for the lifetime of the process object.

When we generate or rescan events, we can again capture a local model variable list in a model instance. This allows us to reweight event by event with different parameter sets simultaneously.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_var_t
      private
      type(string_t) :: name
      integer :: type = V_NONE
      type(parse_node_t), pointer :: pn_value => null ()
      logical :: is_intrinsic = .false.
      logical :: is_copy = .false.
    contains
    ⟨Commands: cmd var: TBP⟩
    end type cmd_var_t
```

Output. We know name, type, and properties, but not the value.

⟨*Commands: cmd var: TBP*⟩≡
```
    procedure :: write => cmd_var_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_var_write (cmd, unit, indent)
      class(cmd_var_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
```

```
      write (u, "(1x,A,A,A)", advance="no")  "var: ", char (cmd%name), " ("
      select case (cmd%type)
      case (V_NONE)
         write (u, "(A)", advance="no")  "[unknown]"
      case (V_LOG)
         write (u, "(A)", advance="no")  "logical"
      case (V_INT)
         write (u, "(A)", advance="no")  "int"
      case (V_REAL)
         write (u, "(A)", advance="no")  "real"
      case (V_CMPLX)
         write (u, "(A)", advance="no")  "complex"
      case (V_STR)
         write (u, "(A)", advance="no")  "string"
      case (V_PDG)
         write (u, "(A)", advance="no")  "alias"
      end select
      if (cmd%is_intrinsic) then
         write (u, "(A)", advance="no")  ", intrinsic"
      end if
      if (cmd%is_copy) then
         write (u, "(A)", advance="no")  ", copy"
      end if
      write (u, "(A)")  ")"
   end subroutine cmd_var_write
```

Compile the lhs and determine the variable name and type. Check whether this variable can be created or modified as requested, and append the value to the variable list, if appropriate. The value is initially undefined. The rhs is assigned to a pointer, to be compiled and evaluated when the command is executed.

      end select
   end subroutine cmd_var_set_value
```

SLHA

Read a SLHA (SUSY Les Houches Accord) file to fill the appropriate model parameters. We do not access the current variable record, but directly work on the appropriate SUSY model, which is loaded if necessary.

We may be in read or write mode. In the latter case, we may write just input parameters, or the complete spectrum, or the spectrum with all decays.

⟨*Commands: types*⟩+≡
```
   type, extends (command_t) :: cmd_slha_t
     private
     type(string_t) :: file
     logical :: write_mode = .false.
    contains
    ⟨Commands: cmd slha: TBP⟩
   end type cmd_slha_t
```

Output.

⟨*Commands: cmd slha: TBP*⟩≡
```
   procedure :: write => cmd_slha_write
```

⟨*Commands: procedures*⟩+≡
```
   subroutine cmd_slha_write (cmd, unit, indent)
     class(cmd_slha_t), intent(in) :: cmd
     integer, intent(in), optional :: unit, indent
     integer :: u
     u = output_unit (unit);  if (u < 0)  return
     call write_indent (u, indent)
     write (u, "(1x,A,A)")  "slha: file name  = ", char (cmd%file)
     write (u, "(1x,A,L1)") "slha: write mode = ", cmd%write_mode
   end subroutine cmd_slha_write
```

Compile. Read the filename and store it.

⟨*Commands: cmd slha: TBP*⟩+≡
```
   procedure :: compile => cmd_slha_compile
```

⟨*Commands: procedures*⟩+≡
```
   subroutine cmd_slha_compile (cmd, global)
     class(cmd_slha_t), intent(inout) :: cmd
     type(rt_data_t), intent(inout), target :: global
     type(parse_node_t), pointer :: pn_key, pn_arg, pn_file
     pn_key => parse_node_get_sub_ptr (cmd%pn)
     pn_arg => parse_node_get_next_ptr (pn_key)
     pn_file => parse_node_get_sub_ptr (pn_arg)
     call cmd%compile_options (global)
     cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
```

```
      select case (char (parse_node_get_key (pn_key)))
      case ("read_slha")
         cmd%write_mode = .false.
      case ("write_slha")
         cmd%write_mode = .true.
      case default
         call parse_node_mismatch ("read_slha|write_slha",  cmd%pn)
      end select
      cmd%file = parse_node_get_string (pn_file)
   end subroutine cmd_slha_compile
```

Execute. Read or write the specified SLHA file. Behind the scenes, this will first read the WHIZARD model file, then read the SLHA file and assign the SLHA parameters as far as determined by `dispatch_slha`. Finally, the global variables are synchronized with the model. This is similar to executing `cmd_model`.

⟨*Commands: cmd slha: TBP*⟩+≡
```
   procedure :: execute => cmd_slha_execute
```

⟨*Commands: procedures*⟩+≡
```
   subroutine cmd_slha_execute (cmd, global)

              input = input, spectrum = spectrum, decays = decays)
     else
        call dispatch_slha (cmd%local, &
             input = input, spectrum = spectrum, decays = decays)
        call slha_read_file &
             (cmd%file, cmd%local%os_data, global%model_list, global%model, &
              input = input, spectrum = spectrum, decays = decays)
        model_vars => model_get_var_list_ptr (global%model)
        call var_list_synchronize (global%var_list, model_vars, &
             reset_pointers = .true.)
        call global%particle_stack%reset (global%model)
     end if
   end subroutine cmd_slha_execute
```

Show values

This command shows the current values of variables or other objects, in a suitably condensed form.

⟨*Commands: types*⟩+≡
```
   type, extends (command_t) :: cmd_show_t
     private
     type(string_t), dimension(:), allocatable :: name
```

```
  contains
⟨Commands: cmd show: TBP⟩
end type cmd_show_t
```

Output: list the object names, not values.

⟨*Commands: cmd show: TBP*⟩≡
```
    procedure :: write => cmd_show_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_show_write (cmd, unit, indent)
      class(cmd_show_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u, i
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)", advance="no")  "show: "
      if (allocated (cmd%name)) then
         do i = 1, size (cmd%name)
            write (u, "(1x,A)", advance="no")  char (cmd%name(i))
         end do
         write (u, *)
      else
         write (u, "(5x,A)")  "[undefined]"
      end if
    end subroutine cmd_show_write
```

Compile. Allocate an array which is filled with the names of the variables to show.

⟨*Commands: cmd show: TBP*⟩+≡
```
    procedure :: compile => cmd_show_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_show_compile (cmd, global)
      class(cmd_show_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_arg, pn_var, pn_prefix, pn_name
      type(string_t) :: key

Clear values

This command clears the current values of variables or other objects, where this
makes sense. It parallels the show command. The objects are cleared, but not
deleted.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_clear_t
      private
      type(string_t), dimension(:), allocatable :: name
     contains
     ⟨Commands: cmd clear: TBP⟩
    end type cmd_clear_t
```

Output: list the names of the objects to be cleared.

⟨*Commands: cmd clear: TBP*⟩≡
```
    procedure :: write => cmd_clear_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_clear_write (cmd, unit, indent)
      class(cmd_clear_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u, i
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)", advance="no")  "clear: "

         end do
      end if
    end subroutine cmd_clear_execute
```

Compare values of variables to expectation

The implementation is similar to the `show` command. There are just two arguments: two values that should be compared. For providing local values for the numerical tolerance, the command has a local argument list.

    If the expectation fails, an error condition is recorded.

⟨*Commands: types*⟩+≡
```
type, extends (command_t) :: cmd_expect_t
   private
   type(parse_node_t), pointer :: pn_lexpr => null ()
 contains
 ⟨Commands: cmd expect: TBP⟩
 end type cmd_expect_t
```

Simply tell the status.

⟨*Commands: cmd expect: TBP*⟩≡
```
procedure :: write => cmd_expect_write
```

⟨*Commands: procedures*⟩+≡
```
subroutine cmd_expect_write (cmd, unit, indent)
  class(cmd_expect_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = output_unit (unit);  if (u < 0)  return
  call write_indent (u, indent)
  if (associated (cmd%pn_lexpr)) then
     write (u, "(1x,A)")  "expect: [expression associated]"
  else
     write (u, "(1x,A)")  "expect: [undefined]"
  end if
end subroutine cmd_expect_write
```

Compile. This merely assigns the parse node, the actual compilation is done at execution. This is necessary because the origin of variables (local/global) may change during execution.

⟨*Commands: cmd expect: TBP*⟩+≡
```
procedure :: compile => cmd_expect_compile
```

⟨*Commands: procedures*⟩+≡
```
subroutine cmd_expect_compile (cmd, global)
  class(cmd_expect_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_arg
  pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
  cmd%pn_opt => parse_node_get_next_ptr (pn_arg)
  cmd%pn_lexpr => parse_node_get_sub_ptr (pn_arg)
  call cmd%compile_options (global)
end subroutine cmd_expect_compile
```

Execute. Evaluate both arguments, print them and their difference (if numerical), and whether they agree. Record the result.

⟨*Commands: cmd expect: TBP*⟩+≡
```
procedure :: execute => cmd_expect_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_expect_execute (cmd, global)
      class(cmd_expect_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      logical :: success, is_known
      success = &
           eval_log (cmd%pn_lexpr, cmd%local%var_list, is_known=is_known)
      if (is_known) then
         if (success) then
            call msg_message ("expect: success")
         else
            call msg_error ("expect: failure")
         end if
      else
         call msg_error ("expect: undefined result")
         success = .false.
      end if
      call expect_record (success)
    end subroutine cmd_expect_execute
```

Beams

The beam command includes both beam and structure-function definition.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_beams_t
      private
      integer :: n_in = 0
      type(parse_node_p), dimension(:), allocatable :: pn_pdg
      integer :: n_sf_record = 0
      integer, dimension(:), allocatable :: n_entry
      type(parse_node_p), dimension(:,:), allocatable :: pn_sf_entry
     contains
     ⟨Commands: cmd beams: TBP⟩
    end type cmd_beams_t
```

Output. The particle expressions are not resolved.

⟨*Commands: cmd beams: TBP*⟩≡
```
    procedure :: write => cmd_beams_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_beams_write (cmd, unit, indent)
      class(cmd_beams_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      select case (cmd%n_in)
      case (1)
         write (u, "(1x,A)")  "beams: 1 [decay]"
      case (2)
         write (u, "(1x,A)")  "beams: 2 [scattering]"
      case default
```

```
           write (u, "(1x,A)")  "beams: [undefined]"
        end select
        if (allocated (cmd%n_entry)) then
           if (cmd%n_sf_record > 0) then
              write (u, "(1x,A,99(1x,I0))")  "structure function entries:", &
                    cmd%n_entry
           end if
        end if
     end subroutine cmd_beams_write
```

Compile. Find and assign the parse nodes.

Note: local environments are not yet supported.

⟨*Commands: cmd beams: TBP*⟩+≡
```
     procedure :: compile => cmd_beams_compile

    end subroutine cmd_beams_execute
```

Density matrices for beam polarization

For holding beam polarization, we define a notation and a data structure for sparse matrices. The entries (and the index expressions) are numerical expressions, so we use evaluation trees.

Each entry in the sparse matrix is an n-tuple of expressions. The first tuple elements represent index values, the last one is an arbitrary (complex) number. Absent expressions are replaced by default-value rules.

Note: Here, and in some other commands, we would like to store an evaluation tree, not just a parse node pointer. However, the current expression handler wants all variables defined, so the evaluation tree can only be built by `evaluate`, i.e., compiled just-in-time and evaluated immediately.

⟨*Commands: types*⟩+≡
```
type :: sentry_expr_t
   type(parse_node_p), dimension(:), allocatable :: expr
 contains
 ⟨Commands: sentry expr: TBP⟩
 end type sentry_expr_t
```

Compile parse nodes into evaluation trees.

⟨*Commands: sentry expr: TBP*⟩≡
```
procedure :: compile => sentry_expr_compile
```

⟨*Commands: procedures*⟩+≡
```
subroutine sentry_expr_compile (sentry, pn)
  class(sentry_expr_t), intent(out) :: sentry
  type(parse_node_t), intent(in), target :: pn
  type(parse_node_t), pointer :: pn_expr, pn_extra
  integer :: n_expr, i
  n_expr = parse_node_get_n_sub (pn)
  allocate (sentry%expr (n_expr))
  if (n_expr > 0) then
     i = 0
     pn_expr => parse_node_get_sub_ptr (pn)
     pn_extra => parse_node_get_next_ptr (pn_expr)
     do i = 1, n_expr
        sentry%expr(i)%ptr => pn_expr
        if (associated (pn_extra)) then
           pn_expr => parse_node_get_sub_ptr (pn_extra, 2)
           pn_extra => parse_node_get_next_ptr (pn_extra)
        end if
     end do
  end if
end subroutine sentry_expr_compile
```

Evaluate the expressions and return an index array of predefined length together with a complex value. If the value (as the last expression) is undefined, set it to unity. If index values are undefined, repeat the previous index value.

⟨*Commands: sentry expr: TBP*⟩+≡
```
procedure :: evaluate => sentry_expr_evaluate
```

⟨*Commands: procedures*⟩+≡
```
subroutine sentry_expr_evaluate (sentry, index, value, global)
```

```
      class(sentry_expr_t), intent(inout) :: sentry
      integer, dimension(:), intent(out) :: index
      complex(default), intent(out) :: value
      type(rt_data_t), intent(in), target :: global

              end if
              call eval_tree_final (eval_tree)
            end associate
         else
              value = 1
         end if
      else
         call msg_fatal ("Evaluating density matrix: index expression too long")
      end if
    end subroutine sentry_expr_evaluate
```

The sparse matrix itself consists of an arbitrary number of entries.
⟨*Commands: types*⟩+≡
```
    type :: smatrix_expr_t
      type(sentry_expr_t), dimension(:), allocatable :: entry
     contains
     ⟨Commands: smatrix expr: TBP⟩
    end type smatrix_expr_t
```

Compile: assign sub-nodes to sentry-expressions and compile those.
⟨*Commands: smatrix expr: TBP*⟩≡
```
    procedure :: compile => smatrix_expr_compile
```

⟨*Commands: procedures*⟩+≡
```
  subroutine smatrix_expr_compile (smatrix_expr, pn)
    class(smatrix_expr_t), intent(out) :: smatrix_expr
    type(parse_node_t), intent(in), target :: pn
    type(parse_node_t), pointer :: pn_arg, pn_entry
    integer :: n_entry, i
    pn_arg => parse_node_get_sub_ptr (pn, 2)
    if (associated (pn_arg)) then
       n_entry = parse_node_get_n_sub (pn_arg)
       allocate (smatrix_expr%entry (n_entry))
       pn_entry => parse_node_get_sub_ptr (pn_arg)
       do i = 1, n_entry
          call smatrix_expr%entry(i)%compile (pn_entry)
          pn_entry => parse_node_get_next_ptr (pn_entry)
       end do
    else
       allocate (smatrix_expr%entry (0))
    end if
  end subroutine smatrix_expr_compile
```

Evaluate the entries and build a new `smatrix` object, which contains just the numerical results.

⟨*Commands: smatrix expr: TBP*⟩+≡
```
  procedure :: evaluate => smatrix_expr_evaluate
```

⟨*Commands: procedures*⟩+≡
```
  subroutine smatrix_expr_evaluate (smatrix_expr, smatrix, global)
    class(smatrix_expr_t), intent(inout) :: smatrix_expr
    type(smatrix_t), intent(out) :: smatrix
    type(rt_data_t), intent(in), target :: global

       call smatrix%set_entry (i, idx, value)
    end do
  end subroutine smatrix_expr_evaluate
```

Beam polarization density

The beam polarization command defines spin density matrix for one or two beams (scattering or decay).

⟨*Commands: types*⟩+≡
```
  type, extends (command_t) :: cmd_beams_pol_density_t
    private
    integer :: n_in = 0
    type(smatrix_expr_t), dimension(:), allocatable :: smatrix
   contains
    ⟨Commands: cmd beams pol density: TBP⟩
```

```
      end type cmd_beams_pol_density_t
```

Output.

⟨*Commands: cmd beams pol density: TBP*⟩≡
```
    procedure :: write => cmd_beams_pol_density_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_beams_pol_density_write (cmd, unit, indent)
      class(cmd_beams_pol_density_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      select case (cmd%n_in)
      case (1)
         write (u, "(1x,A)")  "beams polarization setup: 1 [decay]"
      case (2)
         write (u, "(1x,A)")  "beams polarization setup: 2 [scattering]"
      case default
         write (u, "(1x,A)")  "beams polarization setup: [undefined]"
      end select
    end subroutine cmd_beams_pol_density_write
```

Compile. Find and assign the parse nodes.

Note: local environments are not yet supported.

⟨*Commands: cmd beams pol density: TBP*⟩+≡
```
    procedure :: compile => cmd_beams_pol_density_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_beams_pol_density_compile (cmd, global)
      class(cmd_beams_pol_density_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_pol_spec, pn_smatrix
      integer :: i
      pn_pol_spec => parse_node_get_sub_ptr (cmd%pn, 3)
      call cmd%compile_options (global)
      cmd%n_in = parse_node_get_n_sub (pn_pol_spec)
      allocate (cmd%smatrix (cmd%n_in))
      pn_smatrix => parse_node_get_sub_ptr (pn_pol_spec)
      do i = 1, cmd%n_in
         call cmd%smatrix(i)%compile (pn_smatrix)
         pn_smatrix => parse_node_get_next_ptr (pn_smatrix)
      end do
    end subroutine cmd_beams_pol_density_compile
```

Command execution: Fill polarization density matrices. No check yet, the matrices are checked and normalized when the actual beam object is created, just before integration. For intermediate storage, we use the `beam_structure` object in the `global` data set.

⟨*Commands: cmd beams pol density: TBP*⟩+≡
```
    procedure :: execute => cmd_beams_pol_density_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_beams_pol_density_execute (cmd, global)
      class(cmd_beams_pol_density_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(smatrix_t) :: smatrix
      integer :: i
      call global%beam_structure%init_pol (cmd%n_in)
      do i = 1, cmd%n_in
         call cmd%smatrix(i)%evaluate (smatrix, global)
         call global%beam_structure%set_smatrix (i, smatrix)
      end do
    end subroutine cmd_beams_pol_density_execute
```

Beam polarization fraction

In addition to the polarization density matrix, we can independently specify the polarization fraction for one or both beams.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_beams_pol_fraction_t
      private
      integer :: n_in = 0
      type(parse_node_p), dimension(:), allocatable :: expr
    contains
    ⟨Commands: cmd beams pol fraction: TBP⟩
    end type cmd_beams_pol_fraction_t
```

Output.

⟨*Commands: cmd beams pol fraction: TBP*⟩≡
```
    procedure :: write => cmd_beams_pol_fraction_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_beams_pol_fraction_write (cmd, unit, indent)
      class(cmd_beams_pol_fraction_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      select case (cmd%n_in)
      case (1)
         write (u, "(1x,A)")  "beams polarization fraction: 1 [decay]"
      case (2)
         write (u, "(1x,A)")  "beams polarization fraction: 2 [scattering]"
      case default
         write (u, "(1x,A)")  "beams polarization fraction: [undefined]"
      end select
    end subroutine cmd_beams_pol_fraction_write
```

Compile. Find and assign the parse nodes.

Note: local environments are not yet supported.

⟨*Commands: cmd beams pol fraction: TBP*⟩+≡
```
    procedure :: compile => cmd_beams_pol_fraction_compile
```

3044

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_beams_pol_fraction_compile (cmd, global)
      class(cmd_beams_pol_fraction_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_frac_spec, pn_expr
      integer :: i
      pn_frac_spec => parse_node_get_sub_ptr (cmd%pn, 3)
      call cmd%compile_options (global)
      cmd%n_in = parse_node_get_n_sub (pn_frac_spec)
      allocate (cmd%expr (cmd%n_in))
      pn_expr => parse_node_get_sub_ptr (pn_frac_spec)
      do i = 1, cmd%n_in
         cmd%expr(i)%ptr => pn_expr
         pn_expr => parse_node_get_next_ptr (pn_expr)
      end do
    end subroutine cmd_beams_pol_fraction_compile
```

Command execution: Retrieve the numerical values of the beam polarization fractions. The results are stored in the `beam_structure` component of the `global` data block.

⟨*Commands: cmd beams pol fraction: TBP*⟩+≡
```
    procedure :: execute => cmd_beams_pol_fraction_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_beams_pol_fraction_execute (cmd, global)
      class(cmd_beams_pol_fraction_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      real(default), dimension(:), allocatable :: pol_f
      type(eval_tree_t) :: expr
      integer :: i
      allocate (pol_f (cmd%n_in))
      do i = 1, cmd%n_in
         call eval_tree_init_expr (expr, cmd%expr(i)%ptr, global%var_list)
         call eval_tree_evaluate (expr)
         if (eval_tree_result_is_known (expr)) then
            pol_f(i) = eval_tree_get_real (expr)
         else
            call msg_fatal ("beams polarization fraction: undefined value")
         end if
         call eval_tree_final (expr)
      end do
      call global%beam_structure%set_pol_f (pol_f)
    end subroutine cmd_beams_pol_fraction_execute
```

Beam momentum

This is completely analogous to the previous command, hence we can use inheritance.

⟨*Commands: types*⟩+≡
```
    type, extends (cmd_beams_pol_fraction_t) :: cmd_beams_momentum_t
     contains
```
⟨*Commands: cmd beams momentum: TBP*⟩

3045

```
    end type cmd_beams_momentum_t
```

Output.

⟨*Commands: cmd beams momentum: TBP*⟩≡
```
    procedure :: write => cmd_beams_momentum_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_beams_momentum_write (cmd, unit, indent)
      class(cmd_beams_momentum_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      select case (cmd%n_in)
      case (1)
         write (u, "(1x,A)")  "beams momentum: 1 [decay]"
      case (2)
         write (u, "(1x,A)")  "beams momentum: 2 [scattering]"
      case default
         write (u, "(1x,A)")  "beams momentum: [undefined]"
      end select
    end subroutine cmd_beams_momentum_write
```

Compile: inherited.

Command execution: Not inherited, but just the error string and the final command are changed.

⟨*Commands: cmd beams momentum: TBP*⟩+≡
```
    procedure :: execute => cmd_beams_momentum_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_beams_momentum_execute (cmd, global)
      class(cmd_beams_momentum_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      real(default), dimension(:), allocatable :: p
      type(eval_tree_t) :: expr
      integer :: i
      allocate (p (cmd%n_in))
      do i = 1, cmd%n_in
         call eval_tree_init_expr (expr, cmd%expr(i)%ptr, global%var_list)
         call eval_tree_evaluate (expr)
         if (eval_tree_result_is_known (expr)) then
            p(i) = eval_tree_get_real (expr)
         else
            call msg_fatal ("beams momentum: undefined value")
         end if
         call eval_tree_final (expr)
      end do
      call global%beam_structure%set_momentum (p)
    end subroutine cmd_beams_momentum_execute
```

Beam angles

Again, this is analogous. There are two angles, polar angle θ and azimuthal angle ϕ, which can be set independently for both beams.

⟨*Commands: types*⟩+≡
```
type, extends (cmd_beams_pol_fraction_t) :: cmd_beams_theta_t

     call eval_tree_init_expr (expr, cmd%expr(i)%ptr, global%var_list)
     call eval_tree_evaluate (expr)
     if (eval_tree_result_is_known (expr)) then
        theta(i) = eval_tree_get_real (expr)
     else
        call msg_fatal ("beams theta: undefined value")
     end if
     call eval_tree_final (expr)
  end do
  call global%beam_structure%set_theta (theta)
end subroutine cmd_beams_theta_execute

subroutine cmd_beams_phi_execute (cmd, global)
  class(cmd_beams_phi_t), intent(inout) :: cmd
  type(rt_data_t), intent(inout), target :: global
  real(default), dimension(:), allocatable :: phi
  type(eval_tree_t) :: expr
  integer :: i
  allocate (phi (cmd%n_in))
  do i = 1, cmd%n_in
     call eval_tree_init_expr (expr, cmd%expr(i)%ptr, global%var_list)
     call eval_tree_evaluate (expr)
     if (eval_tree_result_is_known (expr)) then
        phi(i) = eval_tree_get_real (expr)
     else
        call msg_fatal ("beams phi: undefined value")
     end if
     call eval_tree_final (expr)
  end do
  call global%beam_structure%set_phi (phi)
end subroutine cmd_beams_phi_execute
```

Cuts

Define a cut expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the

cut expression is used.

⟨*Commands: types*⟩+≡

```
    type, extends (command_t) :: cmd_cuts_t
      private
      type(parse_node_t), pointer :: pn_lexpr => null ()
     contains
     ⟨Commands: cmd cuts: TBP⟩
    end type cmd_cuts_t
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

⟨*Commands: cmd cuts: TBP*⟩≡

```
    procedure :: write => cmd_cuts_write
```

⟨*Commands: procedures*⟩+≡

```
    subroutine cmd_cuts_write (cmd, unit, indent)
      class(cmd_cuts_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "cuts: [defined]"
    end subroutine cmd_cuts_write
```

Compile. Simply store the parse (sub)tree.

⟨*Commands: cmd cuts: TBP*⟩+≡

```
    procedure :: compile => cmd_cuts_compile
```

⟨*Commands: procedures*⟩+≡

```
    subroutine cmd_cuts_compile (cmd, global)
      class(cmd_cuts_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
    end subroutine cmd_cuts_compile
```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

⟨*Commands: cmd cuts: TBP*⟩+≡

```
    procedure :: execute => cmd_cuts_execute
```

⟨*Commands: procedures*⟩+≡

```
    subroutine cmd_cuts_execute (cmd, global)
      class(cmd_cuts_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      global%pn%cuts_lexpr => cmd%pn_lexpr
    end subroutine cmd_cuts_execute
```

General, Factorization and Renormalization Scales

Define a scale expression for either the renormalization or the factorization scale. We store the parse tree for the right-hand side instead of compiling

it. Compilation is deferred to the process environment where the expression is used.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_scale_t
      private
      type(parse_node_t), pointer :: pn_expr => null ()
     contains
     ⟨Commands: cmd scale: TBP⟩
    end type cmd_scale_t
```

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_fac_scale_t
      private
      type(parse_node_t), pointer :: pn_expr => null ()
     contains
     ⟨Commands: cmd fac scale: TBP⟩
    end type cmd_fac_scale_t
```

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_ren_scale_t
      private
      type(parse_node_t), pointer :: pn_expr => null ()
     contains
     ⟨Commands: cmd ren scale: TBP⟩
    end type cmd_ren_scale_t
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

⟨*Commands: cmd scale: TBP*⟩≡
```
    procedure :: write => cmd_scale_write
```
⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_scale_write (cmd, unit, indent)
      class(cmd_scale_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "scale: [defined]"
    end subroutine cmd_scale_write
```

⟨*Commands: cmd fac scale: TBP*⟩≡
```
    procedure :: write => cmd_fac_scale_write
```
⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_fac_scale_write (cmd, unit, indent)
      class(cmd_fac_scale_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "factorization scale: [defined]"
    end subroutine cmd_fac_scale_write
```

⟨*Commands: cmd ren scale: TBP*⟩≡
```
    procedure :: write => cmd_ren_scale_write
```
⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_ren_scale_write (cmd, unit, indent)
      class(cmd_ren_scale_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "renormalization scale: [defined]"
    end subroutine cmd_ren_scale_write
```

Compile. Simply store the parse (sub)tree.

⟨*Commands: cmd scale: TBP*⟩+≡
```
    procedure :: compile => cmd_scale_compile
```
⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_scale_compile (cmd, global)
      class(cmd_scale_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global

      class(cmd_ren_scale_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      global%pn%ren_scale_expr => cmd%pn_expr
    end subroutine cmd_ren_scale_execute
```

Weight

Define a weight expression. The weight is applied to a process to be integrated, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the expression is used.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_weight_t
      private
      type(parse_node_t), pointer :: pn_expr => null ()
     contains
     ⟨Commands: cmd weight: TBP⟩
    end type cmd_weight_t
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

⟨*Commands: cmd weight: TBP*⟩≡
```
    procedure :: write => cmd_weight_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_weight_write (cmd, unit, indent)
      class(cmd_weight_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "weight expression: [defined]"
    end subroutine cmd_weight_write
```

Compile. Simply store the parse (sub)tree.

⟨*Commands: cmd weight: TBP*⟩+≡
```
    procedure :: compile => cmd_weight_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_weight_compile (cmd, global)
      class(cmd_weight_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
    end subroutine cmd_weight_compile
```

Instead of evaluating the expression, link the parse tree to the global data set,
such that it is compiled and executed in the appropriate process context.

⟨*Commands: cmd weight: TBP*⟩+≡
```
    procedure :: execute => cmd_weight_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_weight_execute (cmd, global)
      class(cmd_weight_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      global%pn%weight_expr => cmd%pn_expr
    end subroutine cmd_weight_execute
```

Selection

Define a selection expression. This is to be applied upon simulation or event-
file rescanning, event by event. We store the parse tree for the right-hand side
instead of compiling it. Compilation is deferred to the environment where the
expression is used.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_selection_t
      private
      type(parse_node_t), pointer :: pn_expr => null ()
     contains
     ⟨Commands: cmd selection: TBP⟩
    end type cmd_selection_t
```

Output. Do not print the parse tree, since this may get cluttered. Just a message
that scale, renormalization and factorization have been defined, respectively.

⟨*Commands: cmd selection: TBP*⟩≡
```
    procedure :: write => cmd_selection_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_selection_write (cmd, unit, indent)
      class(cmd_selection_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "selection expression: [defined]"
    end subroutine cmd_selection_write
```

Compile. Simply store the parse (sub)tree.

⟨*Commands: cmd selection: TBP*⟩+≡
```
    procedure :: compile => cmd_selection_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_selection_compile (cmd, global)
      class(cmd_selection_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
    end subroutine cmd_selection_compile
```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

⟨*Commands: cmd selection: TBP*⟩+≡
```
    procedure :: execute => cmd_selection_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_selection_execute (cmd, global)
      class(cmd_selection_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      global%pn%selection_lexpr => cmd%pn_expr
    end subroutine cmd_selection_execute
```

Reweight

Define a reweight expression. This is to be applied upon simulation or event-file rescanning, event by event. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the environment where the expression is used.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_reweight_t
      private
      type(parse_node_t), pointer :: pn_expr => null ()
     contains
     ⟨Commands: cmd reweight: TBP⟩
    end type cmd_reweight_t
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that scale, renormalization and factorization have been defined, respectively.

⟨*Commands: cmd reweight: TBP*⟩≡
```
    procedure :: write => cmd_reweight_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_reweight_write (cmd, unit, indent)
      class(cmd_reweight_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "reweight expression: [defined]"
    end subroutine cmd_reweight_write
```

Compile. Simply store the parse (sub)tree.

⟨*Commands: cmd reweight: TBP*⟩+≡
```
    procedure :: compile => cmd_reweight_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_reweight_compile (cmd, global)
      class(cmd_reweight_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      cmd%pn_expr => parse_node_get_sub_ptr (cmd%pn, 3)
    end subroutine cmd_reweight_compile
```

Instead of evaluating the expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

⟨*Commands: cmd reweight: TBP*⟩+≡
```
    procedure :: execute => cmd_reweight_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_reweight_execute (cmd, global)
      class(cmd_reweight_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      global%pn%reweight_expr => cmd%pn_expr
    end subroutine cmd_reweight_execute
```

Alternative Simulation Setups

Together with simulation, we can re-evaluate event weights in the context of alternative setups. The `cmd_alt_setup_t` object is designed to hold these setups, which are brace-enclosed command lists. Compilation is deferred to the simulation environment where the setup expression is used.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_alt_setup_t
      private
      type(parse_node_p), dimension(:), allocatable :: setup
    contains
    ⟨Commands: cmd alt setup: TBP⟩
    end type cmd_alt_setup_t
```

Output. Print just a message that the alternative setup list has been defined.

⟨*Commands: cmd alt setup: TBP*⟩≡
```
    procedure :: write => cmd_alt_setup_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_alt_setup_write (cmd, unit, indent)
      class(cmd_alt_setup_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A,I0,A)")  "alt_setup: ", size (cmd%setup), " entries"
    end subroutine cmd_alt_setup_write
```

Compile. Store the parse sub-trees in an array.

⟨*Commands: cmd alt setup: TBP*⟩+≡
```
    procedure :: compile => cmd_alt_setup_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_alt_setup_compile (cmd, global)
      class(cmd_alt_setup_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_list, pn_setup
      integer :: i
      pn_list => parse_node_get_sub_ptr (cmd%pn, 3)
      if (associated (pn_list)) then
         allocate (cmd%setup (parse_node_get_n_sub (pn_list)))
         i = 1
         pn_setup => parse_node_get_sub_ptr (pn_list)
         do while (associated (pn_setup))
            cmd%setup(i)%ptr => pn_setup
            i = i + 1
            pn_setup => parse_node_get_next_ptr (pn_setup)
         end do
      else
         allocate (cmd%setup (0))
      end if
    end subroutine cmd_alt_setup_compile
```

Execute. Transfer the array of command lists to the global environment.

⟨*Commands: cmd alt setup: TBP*⟩+≡
```
    procedure :: execute => cmd_alt_setup_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_alt_setup_execute (cmd, global)
      class(cmd_alt_setup_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      if (allocated (global%pn%alt_setup))  deallocate (global%pn%alt_setup)
      allocate (global%pn%alt_setup (size (cmd%setup)), source = cmd%setup)
    end subroutine cmd_alt_setup_execute
```

Integration

Integrate several processes, consecutively with identical parameters.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_integrate_t
      private
      integer :: n_proc = 0
      type(string_t), dimension(:), allocatable :: process_id
     contains
     ⟨Commands: cmd integrate: TBP⟩
    end type cmd_integrate_t
```

Output: we know the process IDs.

⟨*Commands: cmd integrate: TBP*⟩≡
```
    procedure :: write => cmd_integrate_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_integrate_write (cmd, unit, indent)
      class(cmd_integrate_t), intent(in) :: cmd
```

```
      integer, intent(in), optional :: unit, indent
      integer :: u, i
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)", advance="no")  "integrate ("
      do i = 1, cmd%n_proc
         if (i > 1)  write (u, "(A,1x)", advance="no")  ","
         write (u, "(A)", advance="no")  char (cmd%process_id(i))
      end do
      write (u, "(A)")  ")"
    end subroutine cmd_integrate_write
```

Compile.

⟨*Commands: cmd integrate: TBP*⟩+≡
```
    procedure :: compile => cmd_integrate_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_integrate_compile (cmd, global)
      class(cmd_integrate_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_proclist, pn_proc
      integer :: i
      pn_proclist => parse_node_get_sub_ptr (cmd%pn, 2)
      cmd%pn_opt => parse_node_get_next_ptr (pn_proclist)
      call cmd%compile_options (global)
      cmd%n_proc = parse_node_get_n_sub (pn_proclist)
      allocate (cmd%process_id (cmd%n_proc))
      pn_proc => parse_node_get_sub_ptr (pn_proclist)
      do i = 1, cmd%n_proc
         cmd%process_id(i) = parse_node_get_string (pn_proc)
         call global%process_stack%init_result_vars (cmd%process_id(i))
         pn_proc => parse_node_get_next_ptr (pn_proc)
      end do
    end subroutine cmd_integrate_compile
```

Command execution. Integrate the process(es) with the predefined number of passes, iterations and calls. For structure functions, cuts, weight and scale, use local definitions if present; by default, the local definitions are initialized with the global ones.

Since the process acquires a snapshot of the variable list, so if the global list (or the local one) is deleted, this does no harm. This implies that later changes of the variable list do not affect the stored process.

⟨*Commands: cmd integrate: TBP*⟩+≡
```
    procedure :: execute => cmd_integrate_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_integrate_execute (cmd, global)
      class(cmd_integrate_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      integer :: i
      do i = 1, cmd%n_proc
         call integrate_process (cmd%process_id(i), cmd%local)
         call cmd%local%process_stack%fill_result_vars (cmd%process_id(i))
```

```
        if (signal_is_pending ())  return
      end do
    end subroutine cmd_integrate_execute
```

Observables

Declare an observable. After the declaration, it can be used to record data, and at the end one can retrieve average and error.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_observable_t
      private
      type(string_t) :: id
    contains
    ⟨Commands: cmd observable: TBP⟩
    end type cmd_observable_t
```

Output. We know the ID.

⟨*Commands: cmd observable: TBP*⟩≡
```
    procedure :: write => cmd_observable_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_observable_write (cmd, unit, indent)
      class(cmd_observable_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A,A)")  "observable: ", char (cmd%id)
    end subroutine cmd_observable_write
```

Compile. Just record the observable ID.

⟨*Commands: cmd observable: TBP*⟩+≡
```
    procedure :: compile => cmd_observable_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_observable_compile (cmd, global)
      class(cmd_observable_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_tag
      pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
      if (associated (pn_tag)) then
         cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
      end if
      call cmd%compile_options (global)
      select case (char (parse_node_get_rule_key (pn_tag)))
      case ("analysis_id")
         cmd%id = parse_node_get_string (pn_tag)
      case default
         call msg_bug ("observable: name expression not implemented (yet)")
      end select
    end subroutine cmd_observable_compile
```

Command execution. This declares the observable and allocates it in the analysis store.

⟨*Commands: cmd observable: TBP*⟩+≡
```
    procedure :: execute => cmd_observable_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_observable_execute (cmd, global)
      class(cmd_observable_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(graph_options_t) :: graph_options
      type(string_t) :: label, unit
      label = var_list_get_sval &
           (cmd%local%var_list, var_str ("$obs_label"))
      unit = var_list_get_sval &
           (cmd%local%var_list, var_str ("$obs_unit"))
      call graph_options_init (graph_options)
      call set_graph_options (graph_options, cmd%local%var_list)
      call analysis_init_observable (cmd%id, label, unit, graph_options)
    end subroutine cmd_observable_execute
```

Histograms

Declare a histogram. At minimum, we have to set lower and upper bound and bin width.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_histogram_t
      private
      type(string_t) :: id
      type(parse_node_t), pointer :: pn_lower_bound => null ()
      type(parse_node_t), pointer :: pn_upper_bound => null ()
      type(parse_node_t), pointer :: pn_bin_width => null ()
    contains
    ⟨Commands: cmd histogram: TBP⟩
    end type cmd_histogram_t
```

Output. Just print the ID.

⟨*Commands: cmd histogram: TBP*⟩≡
```
    procedure :: write => cmd_histogram_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_histogram_write (cmd, unit, indent)
      class(cmd_histogram_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A,A)")  "histogram: ", char (cmd%id)
    end subroutine cmd_histogram_write
```

Compile. Record the histogram ID and initialize lower, upper bound and bin width.

⟨*Commands: cmd histogram: TBP*⟩+≡
```
    procedure :: compile => cmd_histogram_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_histogram_compile (cmd, global)

        call drawing_options_set (dro, gmlcode_bg = &
            var_list_get_sval (var_list, var_str ("$gmlcode_bg")))
    end if
    if (var_list_is_known (var_list, var_str ("$gmlcode_fg"))) then
        call drawing_options_set (dro, gmlcode_fg = &
            var_list_get_sval (var_list, var_str ("$gmlcode_fg")))
    end if
  end subroutine set_drawing_options
```

Plots

Declare a plot. No mandatory arguments, just options.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_plot_t
      private
      type(string_t) :: id
    contains
```

⟨*Commands: cmd plot: TBP*⟩
```
    end type cmd_plot_t
```

Output. Just print the ID.

⟨*Commands: cmd plot: TBP*⟩≡
```
    procedure :: write => cmd_plot_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_plot_write (cmd, unit, indent)
      class(cmd_plot_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A,A)")  "plot: ", char (cmd%id)
    end subroutine cmd_plot_write
```

Compile. Record the plot ID and initialize lower, upper bound and bin width.

⟨*Commands: cmd plot: TBP*⟩+≡
```
    procedure :: compile => cmd_plot_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_plot_compile (cmd, global)
      class(cmd_plot_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_tag
      pn_tag => parse_node_get_sub_ptr (cmd%pn, 2)
      cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
      call cmd%init (pn_tag, global)
    end subroutine cmd_plot_compile
```

This init routine is separated because it is reused below for graph initialization.

⟨*Commands: cmd plot: TBP*⟩+≡
```
    procedure :: init => cmd_plot_init
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_plot_init (plot, pn_tag, global)
      class(cmd_plot_t), intent(inout) :: plot
      type(parse_node_t), intent(in), pointer :: pn_tag
      type(rt_data_t), intent(inout), target :: global
      call plot%compile_options (global)
      select case (char (parse_node_get_rule_key (pn_tag)))
      case ("analysis_id")
         plot%id = parse_node_get_string (pn_tag)
      case default
         call msg_bug ("plot: name expression not implemented (yet)")
      end select
    end subroutine cmd_plot_init
```

Command execution. This declares the plot and allocates it in the analysis store.

⟨*Commands: cmd plot: TBP*⟩+≡
```
    procedure :: execute => cmd_plot_execute
```

3064

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_plot_execute (cmd, global)
      class(cmd_plot_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(graph_options_t) :: graph_options
      type(drawing_options_t) :: drawing_options

      call graph_options_init (graph_options)
      call set_graph_options (graph_options, cmd%local%var_list)
      call drawing_options_init_plot (drawing_options)
      call set_drawing_options (drawing_options, cmd%local%var_list)

      call analysis_init_plot (cmd%id, graph_options, drawing_options)
    end subroutine cmd_plot_execute
```

Graphs

Declare a graph. The graph is defined in terms of its contents. Both the graph
and its contents may carry options.

The graph object contains its own ID as well as the IDs of its elements. For
the elements, we reuse the `cmd_plot_t` defined above.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_graph_t
      private
      type(string_t) :: id
      integer :: n_elements = 0
      type(cmd_plot_t), dimension(:), allocatable :: el
      type(string_t), dimension(:), allocatable :: element_id
    contains
    ⟨Commands: cmd graph: TBP⟩
    end type cmd_graph_t
```

Output. Just print the ID.

⟨*Commands: cmd graph: TBP*⟩≡
```
    procedure :: write => cmd_graph_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_graph_write (cmd, unit, indent)
      class(cmd_graph_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A,A,A,I0,A)")  "graph: ", char (cmd%id), &
           " (", cmd%n_elements, " entries)"
    end subroutine cmd_graph_write
```

Compile. Record the graph ID and initialize lower, upper bound and bin width.
For compiling the graph element syntax, we use part of the `cmd_plot_t` com-
piler.

Note: currently, we do not respect options, therefore just IDs on the RHS.

⟨*Commands: cmd graph: TBP*⟩+≡
```
    procedure :: compile => cmd_graph_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_graph_compile (cmd, global)
      class(cmd_graph_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_term, pn_tag, pn_def, pn_app
      integer :: i

      pn_term => parse_node_get_sub_ptr (cmd%pn, 2)
      pn_tag => parse_node_get_sub_ptr (pn_term)
      cmd%pn_opt => parse_node_get_next_ptr (pn_tag)
      call cmd%compile_options (global)
      select case (char (parse_node_get_rule_key (pn_tag)))
      case ("analysis_id")
         cmd%id = parse_node_get_string (pn_tag)
      case default
         call msg_bug ("graph: name expression not implemented (yet)")
      end select
      pn_def => parse_node_get_next_ptr (pn_term, 2)
      cmd%n_elements = parse_node_get_n_sub (pn_def)
      allocate (cmd%element_id (cmd%n_elements))
      allocate (cmd%el (cmd%n_elements))
      pn_term => parse_node_get_sub_ptr (pn_def)
      pn_tag => parse_node_get_sub_ptr (pn_term)
      cmd%el(1)%pn_opt => parse_node_get_next_ptr (pn_tag)
      call cmd%el(1)%init (pn_tag, global)
      cmd%element_id(1) = parse_node_get_string (pn_tag)
      pn_app => parse_node_get_next_ptr (pn_term)
      do i = 2, cmd%n_elements
         pn_term => parse_node_get_sub_ptr (pn_app, 2)
         pn_tag => parse_node_get_sub_ptr (pn_term)
         cmd%el(i)%pn_opt => parse_node_get_next_ptr (pn_tag)
         call cmd%el(i)%init (pn_tag, global)
         cmd%element_id(i) = parse_node_get_string (pn_tag)
         pn_app => parse_node_get_next_ptr (pn_app)
      end do

    end subroutine cmd_graph_compile
```

Command execution. This declares the graph, allocates it in the analysis store, and copies the graph elements.

For the graph, we set graph and default drawing options. For the elements, we reset individual drawing options.

This accesses internals of the contained elements of type `cmd_plot_t`, see above. We might disentangle such an interdependency when this code is rewritten using proper type extension.

⟨*Commands: cmd graph: TBP*⟩+≡
```
    procedure :: execute => cmd_graph_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_graph_execute (cmd, global)
```

```
      class(cmd_graph_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(graph_options_t) :: graph_options
      type(drawing_options_t) :: drawing_options
      integer :: i, type

      call graph_options_init (graph_options)
      call set_graph_options (graph_options, cmd%local%var_list)
      call analysis_init_graph (cmd%id, cmd%n_elements, graph_options)

      do i = 1, cmd%n_elements
         if (associated (cmd%el(i)%options)) then
            call cmd%el(i)%options%execute (cmd%el(i)%local)
         end if
         type = analysis_store_get_object_type (cmd%element_id(i))
         select case (type)
         case (AN_HISTOGRAM)
            call drawing_options_init_histogram (drawing_options)
         case (AN_PLOT)
            call drawing_options_init_plot (drawing_options)
         end select
         call set_drawing_options (drawing_options, cmd%local%var_list)
         if (associated (cmd%el(i)%options)) then
            call set_drawing_options (drawing_options, cmd%el(i)%local%var_list)
         end if
         call analysis_fill_graph (cmd%id, i, cmd%element_id(i), drawing_options)
      end do
    end subroutine cmd_graph_execute
```

Analysis

Hold the analysis ID either as a string or as an expression:

⟨*Commands: types*⟩+≡
```
   type :: analysis_id_t
     type(string_t) :: tag
     type(parse_node_t), pointer :: pn_sexpr => null ()
   end type analysis_id_t
```

Define the analysis expression. We store the parse tree for the right-hand side instead of compiling it. Compilation is deferred to the process environment where the analysis expression is used.

⟨*Commands: types*⟩+≡
```
   type, extends (command_t) :: cmd_analysis_t
     private
     type(parse_node_t), pointer :: pn_lexpr => null ()
   contains
   ⟨Commands: cmd analysis: TBP⟩
   end type cmd_analysis_t
```

Output. Print just a message that analysis has been defined.

⟨*Commands: cmd analysis: TBP*⟩≡

```
    procedure :: write => cmd_analysis_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_analysis_write (cmd, unit, indent)
      class(cmd_analysis_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "analysis: [defined]"
    end subroutine cmd_analysis_write
```

Compile. Simply store the parse (sub)tree.

⟨*Commands: cmd analysis: TBP*⟩+≡
```
    procedure :: compile => cmd_analysis_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_analysis_compile (cmd, global)
      class(cmd_analysis_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      cmd%pn_lexpr => parse_node_get_sub_ptr (cmd%pn, 3)
    end subroutine cmd_analysis_compile
```

Instead of evaluating the cut expression, link the parse tree to the global data set, such that it is compiled and executed in the appropriate process context.

⟨*Commands: cmd analysis: TBP*⟩+≡
```
    procedure :: execute => cmd_analysis_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_analysis_execute (cmd, global)
      class(cmd_analysis_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      global%pn%analysis_lexpr => cmd%pn_lexpr
    end subroutine cmd_analysis_execute
```

Write histograms and plots

The data type encapsulating the command:

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_write_analysis_t
      private
      type(analysis_id_t), dimension(:), allocatable :: id
      type(string_t), dimension(:), allocatable :: tag
     contains
     ⟨Commands: cmd write analysis: TBP⟩
    end type cmd_write_analysis_t
```

Output. Just the keyword.

⟨*Commands: cmd write analysis: TBP*⟩≡
```
    procedure :: write => cmd_write_analysis_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_write_analysis_write (cmd, unit, indent)
      class(cmd_write_analysis_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "write_analysis"
    end subroutine cmd_write_analysis_write
```

Compile.

⟨*Commands: cmd write analysis: TBP*⟩+≡
```
    procedure :: compile => cmd_write_analysis_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_write_analysis_compile (cmd, global)
      class(cmd_write_analysis_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_clause, pn_args, pn_id
      integer :: n, i
      pn_clause => parse_node_get_sub_ptr (cmd%pn)
      pn_args => parse_node_get_sub_ptr (pn_clause, 2)
      cmd%pn_opt => parse_node_get_next_ptr (pn_clause)
      call cmd%compile_options (global)
      if (associated (pn_args)) then
         n = parse_node_get_n_sub (pn_args)
         allocate (cmd%id (n))
         do i = 1, n
            pn_id => parse_node_get_sub_ptr (pn_args, i)
            if (char (parse_node_get_rule_key (pn_id)) == "analysis_id") then
               cmd%id(i)%tag = parse_node_get_string (pn_id)
            else
               cmd%id(i)%pn_sexpr => pn_id
            end if
         end do
      else
         allocate (cmd%id (0))
      end if
    end subroutine cmd_write_analysis_compile
```

The output format for real data values:

⟨*Limits: public parameters*⟩+≡
```
    character(*), parameter, public :: &
         DEFAULT_ANALYSIS_FILENAME = "whizard_analysis.dat"
    character(len=1), dimension(2), parameter, public :: &
         FORBIDDEN_ENDINGS1 = [ "o", "a" ]
    character(len=2), dimension(5), parameter, public :: &
         FORBIDDEN_ENDINGS2 = [ "mp", "ps", "vg", "lo", "la" ]
    character(len=3), dimension(14), parameter, public :: &
         FORBIDDEN_ENDINGS3 = [ "aux", "dvi", "evt", "evx", "f03", "f90", &
             "f95", "log", "ltp", "mpx", "pdf", "phs", "sin", "tex" ]
```

As this contains a lot of similar code to `cmd_compile_analysis_execute` we outsource the main code to a subroutine.

⟨*Commands: cmd write analysis: TBP*⟩+≡
```
    procedure :: execute => cmd_write_analysis_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_write_analysis_execute (cmd, global)
      class(cmd_write_analysis_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      call write_analysis_wrap (cmd%local%var_list, global%out_files, &
           cmd%id, tag = cmd%tag)
    end subroutine cmd_write_analysis_execute
```

If the `data_file` optional argument is present, this is called from `cmd_compile_analysis_execute`, which needs the file name for further processing, and requires the default format. For the moment, parameters and macros for custom data processing are disabled.

⟨*Commands: procedures*⟩+≡
```
    subroutine write_analysis_wrap (var_list, out_files, id, tag, data_file)
      type(var_list_t), intent(inout), target :: var_list
      type(file_list_t), intent(inout), target :: out_files
      type(analysis_id_t), dimension(:), intent(in), target :: id
      type(string_t), dimension(:), allocatable, intent(out) :: tag

   end subroutine write_analysis_wrap
```

Compile analysis results

This command writes files in a form suitable for GAMELAN and executes
the appropriate commands to compile them. The first part is identical to
`cmd_write_analysis`.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_compile_analysis_t
      private
      type(analysis_id_t), dimension(:), allocatable :: id
      type(string_t), dimension(:), allocatable :: tag
    contains
    ⟨Commands: cmd compile analysis: TBP⟩
    end type cmd_compile_analysis_t
```

Output. Just the keyword.

⟨*Commands: cmd compile analysis: TBP*⟩≡
```
    procedure :: write => cmd_compile_analysis_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_compile_analysis_write (cmd, unit, indent)

      call analysis_compile_tex (basename, has_gmlcode, global%os_data)
   end subroutine cmd_compile_analysis_execute
```

23.2 User-controlled output to data files

Open file (output)

Open a file for output.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_open_out_t
      private
      type(parse_node_t), pointer :: file_expr => null ()
    contains
    ⟨Commands: cmd open out: TBP⟩
    end type cmd_open_out_t
```

Finalizer for the embedded eval tree.

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_open_out_final (object)
      class(cmd_open_out_t), intent(inout) :: object
    end subroutine cmd_open_out_final
```

Output (trivial here).

⟨*Commands: cmd open out: TBP*⟩≡
```
    procedure :: write => cmd_open_out_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_open_out_write (cmd, unit, indent)
      class(cmd_open_out_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)", advance="no")  "open_out: <filename>"
    end subroutine cmd_open_out_write
```

Compile: create an eval tree for the filename expression.

⟨*Commands: cmd open out: TBP*⟩+≡
```
    procedure :: compile => cmd_open_out_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_open_out_compile (cmd, global)
      class(cmd_open_out_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      cmd%file_expr => parse_node_get_sub_ptr (cmd%pn, 2)
      if (associated (cmd%file_expr)) then
          cmd%pn_opt => parse_node_get_next_ptr (cmd%file_expr)
      end if
      call cmd%compile_options (global)
    end subroutine cmd_open_out_compile
```

Execute: append the file to the global list of open files.

⟨*Commands: cmd open out: TBP*⟩+≡
```
    procedure :: execute => cmd_open_out_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_open_out_execute (cmd, global)
      class(cmd_open_out_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(eval_tree_t) :: file_expr
      type(string_t) :: file
      call eval_tree_init_sexpr (file_expr, cmd%file_expr, cmd%local%var_list)
      call eval_tree_evaluate (file_expr)
      if (eval_tree_result_is_known (file_expr)) then
          file = eval_tree_get_string (file_expr)
          call file_list_open (global%out_files, file, &
                action = "write", status = "replace", position = "asis")
      else
          call msg_fatal ("open_out: file name argument evaluates to unknown")
      end if
      call eval_tree_final (file_expr)
    end subroutine cmd_open_out_execute
```

Open file (output)

Close an output file. Except for the `execute` method, everything is analogous
to the open command, so we can just inherit.

⟨*Commands: types*⟩+≡
```
    type, extends (cmd_open_out_t) :: cmd_close_out_t
       private
     contains
     ⟨Commands: cmd close out: TBP⟩
    end type cmd_close_out_t
```

Execute: remove the file from the global list of output files.

⟨*Commands: cmd close out: TBP*⟩≡
```
    procedure :: execute => cmd_close_out_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_close_out_execute (cmd, global)
      class(cmd_close_out_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
```

```
    type(eval_tree_t) :: file_expr
    type(string_t) :: file
    call eval_tree_init_sexpr (file_expr, cmd%file_expr, cmd%local%var_list)
    call eval_tree_evaluate (file_expr)
    if (eval_tree_result_is_known (file_expr)) then
       file = eval_tree_get_string (file_expr)
       call file_list_close (global%out_files, file)
    else
       call msg_fatal ("close_out: file name argument evaluates to unknown")
    end if
    call eval_tree_final (file_expr)
end subroutine cmd_close_out_execute
```

23.2.1   Print custom-formatted values

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_printf_t
      private
      type(parse_node_t), pointer :: sexpr => null ()
      type(parse_node_t), pointer :: sprintf_fun => null ()
      type(parse_node_t), pointer :: sprintf_clause => null ()
      type(parse_node_t), pointer :: sprintf => null ()
     contains
     ⟨Commands: cmd printf: TBP⟩
    end type cmd_printf_t
```

Finalize.

⟨*Commands: cmd printf: TBP*⟩≡
```
    procedure :: final => cmd_printf_final
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_printf_final (cmd)
      class(cmd_printf_t), intent(inout) :: cmd
      call parse_node_final (cmd%sexpr, recursive = .false.)
      deallocate (cmd%sexpr)
      call parse_node_final (cmd%sprintf_fun, recursive = .false.)
      deallocate (cmd%sprintf_fun)
      call parse_node_final (cmd%sprintf_clause, recursive = .false.)
      deallocate (cmd%sprintf_clause)
      call parse_node_final (cmd%sprintf, recursive = .false.)
      deallocate (cmd%sprintf)
    end subroutine cmd_printf_final
```

Output. Do not print the parse tree, since this may get cluttered. Just a message that cuts have been defined.

⟨*Commands: cmd printf: TBP*⟩+≡
```
    procedure :: write => cmd_printf_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_printf_write (cmd, unit, indent)
      class(cmd_printf_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
```

```
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)")  "printf:"
    end subroutine cmd_printf_write
```

Compile. We create a fake parse node (subtree) with a `sprintf` command with identical arguments which can then be handled by the corresponding evaluation procedure.

⟨*Commands: cmd printf: TBP*⟩+≡
```
    procedure :: compile => cmd_printf_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_printf_compile (cmd, global)
      class(cmd_printf_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_cmd, pn_clause, pn_args, pn_format
      pn_cmd => parse_node_get_sub_ptr (cmd%pn)
      pn_clause => parse_node_get_sub_ptr (pn_cmd)
      pn_format => parse_node_get_sub_ptr (pn_clause, 2)
      pn_args => parse_node_get_next_ptr (pn_clause)
      cmd%pn_opt => parse_node_get_next_ptr (pn_cmd)
      call cmd%compile_options (global)
      allocate (cmd%sexpr)
      call parse_node_create_branch (cmd%sexpr, &
           syntax_get_rule_ptr (syntax_cmd_list, var_str ("sexpr")))
      allocate (cmd%sprintf_fun)
      call parse_node_create_branch (cmd%sprintf_fun, &
           syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf_fun")))
      allocate (cmd%sprintf_clause)
      call parse_node_create_branch (cmd%sprintf_clause, &
           syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf_clause")))
      allocate (cmd%sprintf)
      call parse_node_create_key (cmd%sprintf, &
           syntax_get_rule_ptr (syntax_cmd_list, var_str ("sprintf")))
      call parse_node_append_sub (cmd%sprintf_clause, cmd%sprintf)
      call parse_node_append_sub (cmd%sprintf_clause, pn_format)
      call parse_node_freeze_branch (cmd%sprintf_clause)
      call parse_node_append_sub (cmd%sprintf_fun, cmd%sprintf_clause)
      if (associated (pn_args)) then
         call parse_node_append_sub (cmd%sprintf_fun, pn_args)
      end if
      call parse_node_freeze_branch (cmd%sprintf_fun)
      call parse_node_append_sub (cmd%sexpr, cmd%sprintf_fun)
      call parse_node_freeze_branch (cmd%sexpr)
    end subroutine cmd_printf_compile
```

Execute. Evaluate the string (pretending this is a `sprintf` expression) and print it.

⟨*Commands: cmd printf: TBP*⟩+≡
```
    procedure :: execute => cmd_printf_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_printf_execute (cmd, global)
```

```
class(cmd_printf_t), intent(inout) :: cmd
type(rt_data_t), intent(inout), target :: global
type(string_t) :: string, file
type(eval_tree_t) :: sprintf_expr
logical :: advance
advance = var_list_get_lval (cmd%local%var_list, &
    var_str ("?out_advance"))
file = var_list_get_sval (cmd%local%var_list, &
    var_str ("$out_file"))
call eval_tree_init_sexpr (sprintf_expr, cmd%sexpr, cmd%local%var_list)
call eval_tree_evaluate (sprintf_expr)
if (eval_tree_result_is_known (sprintf_expr)) then
   string = eval_tree_get_string (sprintf_expr)
   if (len (file) == 0) then
      call msg_result (char (string))
   else
      call file_list_write (global%out_files, file, string, advance)
   end if
end if
end subroutine cmd_printf_execute
```

Record data

The expression syntax already contains a `record` keyword; this evaluates to a logical which is always true, but it has the side-effect of recording data into analysis objects. Here we define a command as an interface to this construct.

⟨*Commands: types*⟩+≡
```
type, extends (command_t) :: cmd_record_t
  private
  type(parse_node_t), pointer :: pn_lexpr => null ()
 contains
 ⟨Commands: cmd record: TBP⟩
end type cmd_record_t
```

Output. With the compile hack below, there is nothing of interest to print here.

⟨*Commands: cmd record: TBP*⟩≡
```
procedure :: write => cmd_record_write
```

⟨*Commands: procedures*⟩+≡
```
subroutine cmd_record_write (cmd, unit, indent)
  class(cmd_record_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = output_unit (unit);  if (u < 0)  return
  call write_indent (u, indent)
  write (u, "(1x,A)")  "record"
end subroutine cmd_record_write
```

Compile. This is a hack which transforms the `record` command into a `record` expression, which we handle in the `expressions` module.

⟨*Commands: cmd record: TBP*⟩+≡
```
procedure :: compile => cmd_record_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_record_compile (cmd, global)
      class(cmd_record_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_lexpr, pn_lsinglet, pn_lterm, pn_record
      call parse_node_create_branch (pn_lexpr, &
           syntax_get_rule_ptr (syntax_cmd_list, var_str ("lexpr")))
      call parse_node_create_branch (pn_lsinglet, &
           syntax_get_rule_ptr (syntax_cmd_list, var_str ("lsinglet")))
      call parse_node_append_sub (pn_lexpr, pn_lsinglet)
      call parse_node_create_branch (pn_lterm, &
           syntax_get_rule_ptr (syntax_cmd_list, var_str ("lterm")))
      call parse_node_append_sub (pn_lsinglet, pn_lterm)
      pn_record => parse_node_get_sub_ptr (cmd%pn)
      call parse_node_append_sub (pn_lterm, pn_record)
      cmd%pn_lexpr => pn_lexpr
    end subroutine cmd_record_compile
```

Command execution. Again, transfer this to the embedded expression and just forget the logical result.

⟨*Commands: cmd record: TBP*⟩+≡
```
    procedure :: execute => cmd_record_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_record_execute (cmd, global)
      class(cmd_record_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      logical :: lval
      lval = eval_log (cmd%pn_lexpr, global%var_list)
    end subroutine cmd_record_execute
```

Unstable particles

Mark a particle as unstable. For each unstable particle, we store a number of decay channels and compute their respective BRs.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_unstable_t
      private
      integer :: n_proc = 0
      type(string_t), dimension(:), allocatable :: process_id
      type(parse_node_t), pointer :: pn_prt_in => null ()
     contains
     ⟨Commands: cmd unstable: TBP⟩
    end type cmd_unstable_t
```

Output: we know the process IDs.

⟨*Commands: cmd unstable: TBP*⟩≡
```
    procedure :: write => cmd_unstable_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_unstable_write (cmd, unit, indent)
      class(cmd_unstable_t), intent(in) :: cmd
```

```
      integer, intent(in), optional :: unit, indent
      integer :: u, i
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A,1x,I0,1x,A)", advance="no")  &
           "unstable:", 1, "("
      do i = 1, cmd%n_proc
         if (i > 1)  write (u, "(A,1x)", advance="no")  ","
         write (u, "(A)", advance="no")  char (cmd%process_id(i))
      end do
      write (u, "(A)")  ")"
   end subroutine cmd_unstable_write
```

Compile. Initiate an eval tree for the decaying particle and determine the decay channel process IDs.

⟨*Commands: cmd unstable: TBP*⟩+≡
```
   procedure :: compile => cmd_unstable_compile
```

⟨*Commands: procedures*⟩+≡
```
   subroutine cmd_unstable_compile (cmd, global)
     class(cmd_unstable_t), intent(inout) :: cmd
     type(rt_data_t), intent(inout), target :: global
     type(parse_node_t), pointer :: pn_list, pn_proc
     integer :: i
     cmd%pn_prt_in => parse_node_get_sub_ptr (cmd%pn, 2)
     pn_list => parse_node_get_next_ptr (cmd%pn_prt_in)
     if (associated (pn_list)) then
        select case (char (parse_node_get_rule_key (pn_list)))
        case ("unstable_arg")
           cmd%n_proc = parse_node_get_n_sub (pn_list)
           cmd%pn_opt => parse_node_get_next_ptr (pn_list)
        case default
           cmd%n_proc = 0
           cmd%pn_opt => pn_list
           pn_list => null ()
        end select
     end if
     call cmd%compile_options (global)
     if (associated (pn_list)) then
        allocate (cmd%process_id (cmd%n_proc))
        pn_proc => parse_node_get_sub_ptr (pn_list)
        do i = 1, cmd%n_proc
           cmd%process_id(i) = parse_node_get_string (pn_proc)
           call cmd%local%process_stack%init_result_vars (cmd%process_id(i))
           pn_proc => parse_node_get_next_ptr (pn_proc)
        end do
     else
        allocate (cmd%process_id (0))
     end if
   end subroutine cmd_unstable_compile
```

Command execution. Evaluate the decaying particle and mark the decays in the current model object.

3080

```

Auto decays: create process IDs and make up process configurations, using the PDG codes generated by the `fs_table` make method.

We allocate and use a self-contained process library that contains only the decay processes of the current particle. When done, we revert the global library pointer to the original library but return the name of the new one. The new library becomes part of the global library stack and can thus be referred to at any time.

⟨*Commands: procedures*⟩+≡

      end do
    end subroutine cmd_stable_execute
```

Polarized particles

These commands mark particles as (un)polarized, to be applied in subsequent simulation passes. Since this is technically the same as the `stable` command, we take a shortcut and make this an extension, just overriding methods.

⟨*Commands: types*⟩+≡
```
    type, extends (cmd_stable_t) :: cmd_polarized_t
     contains
     ⟨Commands: cmd polarized: TBP⟩
    end type cmd_polarized_t

    type, extends (cmd_stable_t) :: cmd_unpolarized_t
     contains
     ⟨Commands: cmd unpolarized: TBP⟩
    end type cmd_unpolarized_t
```

Output: we know only the number of particles.

⟨*Commands: cmd polarized: TBP*⟩≡
```
    procedure :: write => cmd_polarized_write
```

⟨*Commands: cmd unpolarized: TBP*⟩≡
```
    procedure :: write => cmd_unpolarized_write
```

⟨*Commands: procedures*⟩+≡

```
subroutine cmd_polarized_write (cmd, unit, indent)
  class(cmd_polarized_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = output_unit (unit);  if (u < 0)  return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,I0)")  "polarized:", size (cmd%pn_pdg)
end subroutine cmd_polarized_write

subroutine cmd_unpolarized_write (cmd, unit, indent)
  class(cmd_unpolarized_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
  u = output_unit (unit);  if (u < 0)  return
  call write_indent (u, indent)
  write (u, "(1x,A,1x,I0)")  "unpolarized:", size (cmd%pn_pdg)
end subroutine cmd_unpolarized_write
```

Compile: accounted for by the base command.
    Execute: apply the modifications to the current model.

⟨*Commands: cmd polarized: TBP*⟩+≡

```
procedure :: execute => cmd_polarized_execute
```

⟨*Commands: cmd unpolarized: TBP*⟩+≡

    end subroutine cmd_unpolarized_execute
```

Parameters: formats for event-sample output

Specify all event formats that are to be used for output files in the subsequent simulation run. (The raw format is on by default and can be turned off here.)

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_sample_format_t
      private
      type(string_t), dimension(:), allocatable :: format
    contains
    ⟨Commands: cmd sample format: TBP⟩
    end type cmd_sample_format_t
```

Output: here, everything is known.

⟨*Commands: cmd sample format: TBP*⟩≡
```
    procedure :: write => cmd_sample_format_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_sample_format_write (cmd, unit, indent)
      class(cmd_sample_format_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u, i
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)", advance="no")  "sample_format = "
      do i = 1, size (cmd%format)
         if (i > 1)  write (u, "(A,1x)", advance="no")  ","
         write (u, "(A)", advance="no")  char (cmd%format(i))
      end do
      write (u, "(A)")
    end subroutine cmd_sample_format_write
```

Compile. Initialize evaluation trees.

⟨*Commands: cmd sample format: TBP*⟩+≡
```
    procedure :: compile => cmd_sample_format_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_sample_format_compile (cmd, global)
      class(cmd_sample_format_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_arg
      type(parse_node_t), pointer :: pn_format
      integer :: i, n_format
      pn_arg => parse_node_get_sub_ptr (cmd%pn, 3)
      if (associated (pn_arg)) then
         n_format = parse_node_get_n_sub (pn_arg)
         allocate (cmd%format (n_format))
         pn_format => parse_node_get_sub_ptr (pn_arg)
         i = 0
         do while (associated (pn_format))
            i = i + 1
            cmd%format(i) = parse_node_get_string (pn_format)
            pn_format => parse_node_get_next_ptr (pn_format)
         end do
      else
         allocate (cmd%format (0))
      end if
    end subroutine cmd_sample_format_compile
```

Execute. Transfer the list of format specifications to the corresponding array in the runtime data set.

⟨*Commands: cmd sample format: TBP*⟩+≡
```
    procedure :: execute => cmd_sample_format_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_sample_format_execute (cmd, global)
      class(cmd_sample_format_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      if (allocated (global%sample_fmt))  deallocate (global%sample_fmt)
      allocate (global%sample_fmt (size (cmd%format)), source = cmd%format)
    end subroutine cmd_sample_format_execute
```

The simulate command

This is the actual SINDARIN command.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_simulate_t
      ! not private anymore as required by the whizard-c-interface
      integer :: n_proc = 0
      type(string_t), dimension(:), allocatable :: process_id
     contains
     ⟨Commands: cmd simulate: TBP⟩
    end type cmd_simulate_t
```

Output: we know the process IDs.

⟨*Commands: cmd simulate: TBP*⟩≡
```
    procedure :: write => cmd_simulate_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_simulate_write (cmd, unit, indent)
      class(cmd_simulate_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u, i
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A)", advance="no")  "simulate ("
      do i = 1, cmd%n_proc
         if (i > 1)  write (u, "(A,1x)", advance="no")  ","
         write (u, "(A)", advance="no")  char (cmd%process_id(i))
      end do
      write (u, "(A)")  ")"
    end subroutine cmd_simulate_write
```

Compile. In contrast to WHIZARD 1 the confusing option to give the number
of unweighted events for weighted events as if unweighting were to take place has
been abandoned. (We both use `n_events` for weighted and unweighted events,
the variable `n_calls` from WHIZARD 1 has been discarded.

      end do
    end subroutine cmd_simulate_compile
```

Execute command: Simulate events. This is done via a `simulation_t` object
and its associated methods.

Signal handling: the `generate` method may exit abnormally if there is a
pending signal. The current logic ensures that the `es_array` output channels
are closed before the `execute` routine returns. The program will terminate then
in `command_list_execute`.

```

Build an alternative setup: the parse tree is stored in the global environment.
We create a temporary command list to compile and execute this; the result
is an alternative local environment `alt_env` which we can hand over to the
`simulate` command.

⟨*Commands: procedures*⟩+≡
```
   recursive subroutine build_alt_setup (alt_env, global, pn)
     type(rt_data_t), intent(inout), target :: alt_env
     type(rt_data_t), intent(inout), target :: global
     type(parse_node_t), intent(in), target :: pn
     type(command_list_t), allocatable :: alt_options
     allocate (alt_options)
     call alt_env%local_init (global)
     call alt_env%link (global)
     call alt_options%compile (pn, alt_env)
     call alt_options%execute (alt_env)
     call global%restore (alt_env, keep_local = .true.)
     call alt_options%final ()
   end subroutine build_alt_setup
```

The rescan command

This is the actual SINDARIN command.

⟨*Commands: types*⟩+≡
```
type, extends (command_t) :: cmd_rescan_t
  ! private
  type(parse_node_t), pointer :: pn_filename => null ()
  integer :: n_proc = 0
  type(string_t), dimension(:), allocatable :: process_id
 contains
 ⟨Commands: cmd rescan: TBP⟩
end type cmd_rescan_t
```

Output: we know the process IDs.

⟨*Commands: cmd rescan: TBP*⟩≡
```
procedure :: write => cmd_rescan_write
```

⟨*Commands: procedures*⟩+≡
```
subroutine cmd_rescan_write (cmd, unit, indent)
  class(cmd_rescan_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u, i
  u = output_unit (unit);  if (u < 0)  return
  call write_indent (u, indent)
  write (u, "(1x,A)", advance="no")  "rescan ("
  do i = 1, cmd%n_proc
     if (i > 1)  write (u, "(A,1x)", advance="no")  ","
     write (u, "(A)", advance="no")  char (cmd%process_id(i))
  end do
  write (u, "(A)")  ")"
end subroutine cmd_rescan_write
```

Compile. The command takes a suffix argument, namely the file name of requested event file.

         end if
      end do
      call global%it_list%init (n_it, n_calls, custom_adapt, adapt_code)
```

```
        end subroutine cmd_iterations_execute
```

Range expressions

We need a special type for storing and evaluating range expressions.

⟨*Commands: parameters*⟩≡
```
    integer, parameter :: STEP_NONE = 0
    integer, parameter :: STEP_ADD = 1
    integer, parameter :: STEP_SUB = 2
    integer, parameter :: STEP_MUL = 3
    integer, parameter :: STEP_DIV = 4
    integer, parameter :: STEP_COMP_ADD = 11
    integer, parameter :: STEP_COMP_MUL = 13
```

There is an abstract base type and two implementations: scan over integers and scan over reals.

⟨*Commands: types*⟩+≡
```
    type, abstract :: range_t
      type(parse_node_t), pointer :: pn_expr => null ()
      type(parse_node_t), pointer :: pn_term => null ()
      type(parse_node_t), pointer :: pn_factor => null ()
      type(parse_node_t), pointer :: pn_value => null ()
      type(parse_node_t), pointer :: pn_literal => null ()
      type(parse_node_t), pointer :: pn_beg => null ()
      type(parse_node_t), pointer :: pn_end => null ()
      type(parse_node_t), pointer :: pn_step => null ()
      type(eval_tree_t) :: expr_beg
      type(eval_tree_t) :: expr_end
      type(eval_tree_t) :: expr_step
      integer :: step_mode = 0
      integer :: n_step = 0
    contains
    ⟨Commands: range: TBP⟩
    end type range_t
```

These are the implementations:

⟨*Commands: types*⟩+≡
```
    type, extends (range_t) :: range_int_t
      integer :: i_beg = 0
      integer :: i_end = 0
      integer :: i_step = 0
    contains
    ⟨Commands: range int: TBP⟩
  end type range_int_t

    type, extends (range_t) :: range_real_t
      real(default) :: r_beg = 0
      real(default) :: r_end = 0
      real(default) :: r_step = 0
      real(default) :: lr_beg  = 0
      real(default) :: lr_end  = 0
      real(default) :: lr_step = 0
```

```
      contains
```
⟨*Commands: range real: TBP*⟩
```
  end type range_real_t
```

Finalize the allocated dummy node. The other nodes are just pointers.

⟨*Commands: range: TBP*⟩≡
```
    procedure :: final => range_final
```

```

This method manually creates a parse node (actually, a cascade of parse nodes) that hold a constant value as a literal. The idea is that this node is inserted as the right-hand side of a fake variable assignment, which is prepended to each scan iteration. Before the variable assignment is compiled and executed, we can manually reset the value of the literal and thus pretend that the loop variable is assigned this value.

Evaluate: compute the actual bounds and parameters that determine the values
that we can iterate.

This is implementation-specific.

⟨*Commands: range: TBP*⟩+≡

```
procedure (range_evaluate), deferred :: evaluate
```

⟨*Commands: interfaces*⟩+≡

```
abstract interface
   subroutine range_evaluate (range)
     import
     class(range_t), intent(inout) :: range
   end subroutine range_evaluate
end interface
```

The version for an integer variable. If the step is subtractive, we invert the
sign and treat it as an additive step. For a multiplicative step, the step must
be greater than one, and the initial and final values must be of same sign and
strictly ordered. Analogously for a division step.

```

Return the number of iterations:

⟨*Commands: range: TBP*⟩+≡
```
    procedure :: get_n_iterations => range_get_n_iterations
```

⟨*Commands: procedures*⟩+≡
```
    function range_get_n_iterations (range) result (n)
      class(range_t), intent(in) :: range
      integer :: n
      n = range%n_step
    end function range_get_n_iterations
```

Compute the value for iteration i and store it in the embedded token.

⟨*Commands: range: TBP*⟩+≡

```
        procedure (range_set_value), deferred :: set_value
```

⟨*Commands: interfaces*⟩+≡
```
    abstract interface
       subroutine range_set_value (range, i)
         import
         class(range_t), intent(inout) :: range
         integer, intent(in) :: i
       end subroutine range_set_value
    end interface
```

In the integer case, we compute the value directly for additive step. For multiplicative step, we perform a loop in the same way as above, where the number of iteration was determined.

⟨*Commands: range int: TBP*⟩+≡
```
    procedure :: set_value => range_int_set_value
```

⟨*Commands: procedures*⟩+≡
```
    subroutine range_int_set_value (range, i)
      class(range_int_t), intent(inout) :: range

   end select
   call parse_node_set_value (range%pn_literal, rval = rval)
 end subroutine range_real_set_value
```

Scan over parameters and other objects

The scan command allocates a new parse node for the variable assignment (the
lhs). The rhs of this parse node is assigned from the available rhs expressions
in the scan list, one at a time, so the compiled parse node can be prepended to
the scan body.

Note: for the integer/real range array, the obvious implementation as a
polymorphic array is suspended because in gfortran 4.7, polymorphic arrays are
apparently broken.

⟨*Commands: types*⟩+≡
```
   type, extends (command_t) :: cmd_scan_t
     private
     type(string_t) :: name
     integer :: n_values = 0
     type(parse_node_p), dimension(:), allocatable :: scan_cmd
     !!! !!! gfortran 4.7.x memory corruption
     !!!  class(range_t), dimension(:), allocatable :: range
     type(range_int_t), dimension(:), allocatable :: range_int
     type(range_real_t), dimension(:), allocatable :: range_real
   contains
   ⟨Commands: cmd scan: TBP⟩
   end type cmd_scan_t
```

Finalizer.

The auxiliary parse nodes that we have constructed have to be treated carefully: the embedded pointers all point to persistent objects somewhere else and should not be finalized, so we should not call the finalizer recursively.

⟨*Commands: cmd scan: TBP*⟩≡
```
procedure :: final => cmd_scan_final
```

⟨*Commands: procedures*⟩+≡
```
recursive subroutine cmd_scan_final (cmd)
  class(cmd_scan_t), intent(inout) :: cmd
  type(parse_node_t), pointer :: pn_var_single, pn_decl_single
  type(string_t) :: key
  integer :: i
  if (allocated (cmd%scan_cmd)) then
     do i = 1, size (cmd%scan_cmd)
        pn_var_single => parse_node_get_sub_ptr (cmd%scan_cmd(i)%ptr)
        key = parse_node_get_rule_key (pn_var_single)
        select case (char (key))
        case ("scan_string_decl", "scan_log_decl")
           pn_decl_single => parse_node_get_sub_ptr (pn_var_single, 2)
           call parse_node_final (pn_decl_single, recursive=.false.)
           deallocate (pn_decl_single)
        end select
        call parse_node_final (pn_var_single, recursive=.false.)
        deallocate (pn_var_single)
     end do
     deallocate (cmd%scan_cmd)
  end if
  !!! !!! gfortran 4.7.x memory corruption
  !!!  if (allocated (cmd%range)) then
  !!!     do i = 1, size (cmd%range)
  !!!        call cmd%range(i)%final ()
  !!!     end do
  !!!  end if
  if (allocated (cmd%range_int)) then
     do i = 1, size (cmd%range_int)
        call cmd%range_int(i)%final ()
     end do
  end if
  if (allocated (cmd%range_real)) then
     do i = 1, size (cmd%range_real)
        call cmd%range_real(i)%final ()
     end do
  end if
end subroutine cmd_scan_final
```

Output.

⟨*Commands: cmd scan: TBP*⟩+≡
```
procedure :: write => cmd_scan_write
```

⟨*Commands: procedures*⟩+≡
```
subroutine cmd_scan_write (cmd, unit, indent)
  class(cmd_scan_t), intent(in) :: cmd
  integer, intent(in), optional :: unit, indent
  integer :: u
```

```
      u = output_unit (unit);  if (u < 0)  return
      call write_indent (u, indent)
      write (u, "(1x,A,1x,A,1x,'(',I0,')')")  "scan:", char (cmd%name), &
           cmd%n_values
   end subroutine cmd_scan_write
```

Compile the scan command. We construct a new parse node that implements the variable assignment for a single element on the rhs, instead of the whole list that we get from the original parse tree. By simply copying the node, we copy all pointers and inherit the targets from the original. During execution, we should replace the rhs by the stored rhs pointers (the list elements), one by one, then (re)compile the redefined node.

⟨*Commands: cmd scan: TBP*⟩+≡

              end do
              print *, "original"
              call parse_node_write_rec (cmd%pn)
           end if
         end subroutine cmd_scan_compile
```

Execute the loop for all values in the step list. We use the parse trees with single variable assignment that we have stored, to iteratively create a local environment, execute the stored commands, and destroy it again. When we encounter a range object, we execute the commands for each value that this object provides. Computing this value has the side effect of modifying the rhs of the variable assignment that heads the local command list, directly in the local parse tree.

⟨*Commands: cmd scan: TBP*⟩+≡
```
       procedure :: execute => cmd_scan_execute
```
⟨*Commands: procedures*⟩+≡
```
       recursive subroutine cmd_scan_execute (cmd, global)
         class(cmd_scan_t), intent(inout) :: cmd
         type(rt_data_t), intent(inout), target :: global
         type(rt_data_t), allocatable :: local
         integer :: i, j
         do i = 1, cmd%n_values
            if (allocated (cmd%range_int)) then
               call cmd%range_int(i)%compile (global)
               call cmd%range_int(i)%evaluate ()
               do j = 1, cmd%range_int(i)%get_n_iterations ()
                  call cmd%range_int(i)%set_value (j)
                  allocate (local)
                  call build_alt_setup (local, global, cmd%scan_cmd(i)%ptr)
                  deallocate (local)
               end do
            else if (allocated (cmd%range_real)) then

               call cmd%range_real(i)%evaluate ()
               do j = 1, cmd%range_real(i)%get_n_iterations ()
                  call cmd%range_real(i)%set_value (j)
                  allocate (local)
                  call build_alt_setup (local, global, cmd%scan_cmd(i)%ptr)
```

```
         deallocate (local)
      end do
   else
      allocate (local)
      call build_alt_setup (local, global, cmd%scan_cmd(i)%ptr)
      deallocate (local)
   end if
  end do
end subroutine cmd_scan_execute
```

Conditionals

Conditionals are implemented as a list that is compiled and evaluated recursively; this allows for a straightforward representation of `else if` constructs. A `cmd_if_t` object can hold either an `else_if` clause which is another object of this type, or an `else_body`, but not both.

If- or else-bodies are no scoping units, so all data remain global and no copy-in copy-out is needed.

⟨*Commands: types*⟩+≡
```
   type, extends (command_t) :: cmd_if_t
     private
     type(parse_node_t), pointer :: pn_if_lexpr => null ()
     type(command_list_t), pointer :: if_body => null ()
     type(cmd_if_t), dimension(:), pointer :: elsif_cmd => null ()
     type(command_list_t), pointer :: else_body => null ()
    contains
    ⟨Commands: cmd if: TBP⟩
   end type cmd_if_t
```

Finalizer. There are no local options, therefore we can simply override the default finalizer.

⟨*Commands: cmd if: TBP*⟩≡
```
   procedure :: final => cmd_if_final
```

⟨*Commands: procedures*⟩+≡
```
   recursive subroutine cmd_if_final (cmd)
     class(cmd_if_t), intent(inout) :: cmd
     integer :: i
     if (associated (cmd%if_body)) then
        call command_list_final (cmd%if_body)
        deallocate (cmd%if_body)
     end if
     if (associated (cmd%elsif_cmd)) then
        do i = 1, size (cmd%elsif_cmd)
           call cmd_if_final (cmd%elsif_cmd(i))
        end do
        deallocate (cmd%elsif_cmd)
     end if
     if (associated (cmd%else_body)) then
        call command_list_final (cmd%else_body)
        deallocate (cmd%else_body)
     end if
```

```
      end subroutine cmd_if_final
```

Output. Recursively write the command lists.

⟨*Commands: cmd if: TBP*⟩+≡
```
    procedure :: write => cmd_if_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_if_write (cmd, unit, indent)
      class(cmd_if_t), intent(in) :: cmd

     end subroutine error_undecided
   end subroutine cmd_if_execute
```

Include another command-list file

The include command allocates a local parse tree. This must not be deleted before the command object itself is deleted, since pointers may point to subobjects of it.

⟨*Commands: types*⟩+≡
```
   type, extends (command_t) :: cmd_include_t
     private
     type(string_t) :: file
     type(command_list_t), pointer :: command_list => null ()
     type(parse_tree_t) :: parse_tree
    contains
    ⟨Commands: cmd include: TBP⟩
   end type cmd_include_t
```

Finalizer: delete the command list. No options, so we can simply override the default finalizer.

⟨*Commands: cmd include: TBP*⟩≡
```
   procedure :: final => cmd_include_final
```

⟨*Commands: procedures*⟩+≡
```
   subroutine cmd_include_final (cmd)
     class(cmd_include_t), intent(inout) :: cmd
     call parse_tree_final (cmd%parse_tree)
```

```
      if (associated (cmd%command_list)) then
         call cmd%command_list%final ()
         deallocate (cmd%command_list)
      end if
   end subroutine cmd_include_final
```

Write: display the command list as-is, if allocated.

⟨*Commands: cmd include: TBP*⟩+≡
```
   procedure :: write => cmd_include_write
```

⟨*Commands: procedures*⟩+≡
```
   subroutine cmd_include_write (cmd, unit, indent)
     class(cmd_include_t), intent(in) :: cmd
     integer, intent(in), optional :: unit, indent
     integer :: u, ind
     u = output_unit (unit)
     ind = 0;  if (present (indent))  ind = indent
     call write_indent (u, indent)
     write (u, "(A,A,A,A)")  "include ", ’"’, char (cmd%file), ’"’
     if (associated (cmd%command_list)) then
        call cmd%command_list%write (u, ind + 1)
     end if
   end subroutine cmd_include_write
```

Compile file contents: First parse the file, then immediately compile its contents.
Use the global data set.

⟨*Commands: cmd include: TBP*⟩+≡
```
   procedure :: compile => cmd_include_compile
```

⟨*Commands: procedures*⟩+≡
```
   subroutine cmd_include_compile (cmd, global)
     class(cmd_include_t), intent(inout) :: cmd
     type(rt_data_t), intent(inout), target :: global
     type(parse_node_t), pointer :: pn_arg, pn_file
     type(string_t) :: file
     logical :: exist
     integer :: u
     type(stream_t), target :: stream
     type(lexer_t) :: lexer
     pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
     pn_file => parse_node_get_sub_ptr (pn_arg)
     file = parse_node_get_string (pn_file)
     inquire (file=char(file), exist=exist)
     if (exist) then
        cmd%file = file
     else
        cmd%file = global%os_data%whizard_cutspath // "/" // file
        inquire (file=char(cmd%file), exist=exist)
        if (.not. exist) then
           call msg_error ("Include file ’" // char (file) // "’ not found")
           return
        end if
     end if
     u = free_unit ()
```

```
    call lexer_init_cmd_list (lexer, global%lexer)
    call stream_init (stream, char (cmd%file))
    call lexer_assign_stream (lexer, stream)
    call parse_tree_init (cmd%parse_tree, syntax_cmd_list, lexer)
    call stream_final (stream)
    call lexer_final (lexer)
    close (u)
    allocate (cmd%command_list)
    call cmd%command_list%compile (parse_tree_get_root_ptr (cmd%parse_tree), &
        global)
  end subroutine cmd_include_compile
```

Execute file contents in the global context.

⟨*Commands: cmd include: TBP*⟩+≡
```
    procedure :: execute => cmd_include_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_include_execute (cmd, global)
      class(cmd_include_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      if (associated (cmd%command_list)) then
         call msg_message &
              ("Including Sindarin from '" // char (cmd%file) // "'")
         call cmd%command_list%execute (global)
         call msg_message &
              ("End of included '" // char (cmd%file) // "'")
      end if
    end subroutine cmd_include_execute
```

Quit command execution

The code is the return code of the whole program if it is terminated by this command.

⟨*Commands: types*⟩+≡
```
    type, extends (command_t) :: cmd_quit_t
      private
      logical :: has_code = .false.
      type(parse_node_t), pointer :: pn_code_expr => null ()
     contains
     ⟨Commands: cmd quit: TBP⟩
    end type cmd_quit_t
```

Output.

⟨*Commands: cmd quit: TBP*⟩≡
```
    procedure :: write => cmd_quit_write
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_quit_write (cmd, unit, indent)
      class(cmd_quit_t), intent(in) :: cmd
      integer, intent(in), optional :: unit, indent
      integer :: u
      u = output_unit (unit);  if (u < 0)  return
```

```
      call write_indent (u, indent)
      write (u, "(1x,A,L1)")  "quit: has_code = ", cmd%has_code
    end subroutine cmd_quit_write
```

Compile: allocate a `quit` object which serves as a placeholder.

⟨*Commands: cmd quit: TBP*⟩+≡
```
    procedure :: compile => cmd_quit_compile
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_quit_compile (cmd, global)
      class(cmd_quit_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      type(parse_node_t), pointer :: pn_arg
      pn_arg => parse_node_get_sub_ptr (cmd%pn, 2)
      if (associated (pn_arg)) then
         cmd%pn_code_expr => parse_node_get_sub_ptr (pn_arg)
         cmd%has_code = .true.
      end if
    end subroutine cmd_quit_compile
```

Execute: The quit command does not execute anything, it just stops command execution. This is achieved by setting quit flag and quit code in the global variable list. However, the return code, if present, is an expression which has to be evaluated.

⟨*Commands: cmd quit: TBP*⟩+≡
```
    procedure :: execute => cmd_quit_execute
```

⟨*Commands: procedures*⟩+≡
```
    subroutine cmd_quit_execute (cmd, global)
      class(cmd_quit_t), intent(inout) :: cmd
      type(rt_data_t), intent(inout), target :: global
      logical :: is_known
      if (cmd%has_code) then
         global%quit_code = eval_int (cmd%pn_code_expr, global%var_list, &
              is_known=is_known)
         if (.not. is_known) then
            call msg_error ("Undefined return code of quit/exit command")
         end if
      end if
      global%quit = .true.
    end subroutine cmd_quit_execute
```

23.2.2   The command list

The command list holds a list of commands and relevant global data.

⟨*Commands: public*⟩+≡
```
    public :: command_list_t
```

⟨*Commands: types*⟩+≡
```
    type :: command_list_t
       ! not private anymore as required by the whizard-c-interface
       class(command_t), pointer :: first => null ()
```

```
      class(command_t), pointer :: last => null ()
    contains
    ⟨Commands: command list: TBP⟩
  end type command_list_t
```

Output.

⟨*Commands: command list: TBP*⟩≡
```
    procedure :: write => command_list_write
```

⟨*Commands: procedures*⟩+≡
```
    recursive subroutine command_list_write (cmd_list, unit, indent)
      class(command_list_t), intent(in) :: cmd_list
      integer, intent(in), optional :: unit, indent
      class(command_t), pointer :: cmd
      cmd => cmd_list%first
      do while (associated (cmd))
        call cmd%write (unit, indent)
        cmd => cmd%next
      end do
    end subroutine command_list_write
```

Append a new command to the list and free the original pointer.

⟨*Commands: command list: TBP*⟩+≡
```
    procedure :: append => command_list_append
```

⟨*Commands: procedures*⟩+≡
```
    subroutine command_list_append (cmd_list, command)
      class(command_list_t), intent(inout) :: cmd_list
      class(command_t), intent(inout), pointer :: command
      if (associated (cmd_list%last)) then
        cmd_list%last%next => command
      else
        cmd_list%first => command
      end if
      cmd_list%last => command
      command => null ()
    end subroutine command_list_append
```

Finalize.

⟨*Commands: command list: TBP*⟩+≡
```
    procedure :: final => command_list_final
```

⟨*Commands: procedures*⟩+≡
```
    recursive subroutine command_list_final (cmd_list)
      class(command_list_t), intent(inout) :: cmd_list
      class(command_t), pointer :: command
      do while (associated (cmd_list%first))
        command => cmd_list%first
        cmd_list%first => cmd_list%first%next
        call command%final ()
        deallocate (command)
      end do
      cmd_list%last => null ()
    end subroutine command_list_final
```

23.2.3 Compiling the parse tree

Transform a parse tree into a command list. Initialization is assumed to be done.

After each command, we set a breakpoint.

⟨*Commands: command list: TBP*⟩+≡

```
procedure :: compile => command_list_compile
```

⟨*Commands: procedures*⟩+≡

```
recursive subroutine command_list_compile (cmd_list, pn, global)
  class(command_list_t), intent(inout), target :: cmd_list
  type(parse_node_t), intent(in), target :: pn
  type(rt_data_t), intent(inout), target :: global
  type(parse_node_t), pointer :: pn_cmd
  class(command_t), pointer :: command
  integer :: i
  pn_cmd => parse_node_get_sub_ptr (pn)
  do i = 1, parse_node_get_n_sub (pn)
     call dispatch_command (command, pn_cmd)
     call command%compile (global)
     call cmd_list%append (command)
     call terminate_now_if_signal ()
     pn_cmd => parse_node_get_next_ptr (pn_cmd)
  end do
end subroutine command_list_compile
```

23.2.4 Executing the command list

Before executing a command we should execute its options (if any). After that, reset the options, i.e., remove temporary effects from the global state.

Also here, after each command we set a breakpoint.

⟨*Commands: command list: TBP*⟩+≡

```
procedure :: execute => command_list_execute
```

⟨*Commands: procedures*⟩+≡

```
recursive subroutine command_list_execute (cmd_list, global)
  class(command_list_t), intent(in) :: cmd_list
  type(rt_data_t), intent(inout), target :: global
  class(command_t), pointer :: command
  command => cmd_list%first
  COMMAND_COND: do while (associated (command))
     call command%execute_options (global)
     call command%execute (global)
     call command%reset_options (global)
     call terminate_now_if_signal ()
     if (global%quit)  exit COMMAND_COND
     command => command%next
  end do COMMAND_COND
end subroutine command_list_execute
```

23.2.5 Command list syntax

⟨*Commands: public*⟩+≡
```
    public :: syntax_cmd_list
```

⟨*Commands: variables*⟩≡
```
    type(syntax_t), target, save :: syntax_cmd_list
```

⟨*Commands: public*⟩+≡
```
    public :: syntax_cmd_list_init
```

⟨*Commands: procedures*⟩+≡
```
    subroutine syntax_cmd_list_init ()
      type(ifile_t) :: ifile
      call define_cmd_list_syntax (ifile)
      call syntax_init (syntax_cmd_list, ifile)
      call ifile_final (ifile)
    end subroutine syntax_cmd_list_init
```

⟨*Commands: public*⟩+≡
```
    public :: syntax_cmd_list_final
```

⟨*Commands: procedures*⟩+≡
```
    subroutine syntax_cmd_list_final ()
      call syntax_final (syntax_cmd_list)
    end subroutine syntax_cmd_list_final
```

⟨*Commands: public*⟩+≡
```
    public :: syntax_cmd_list_write
```

⟨*Commands: procedures*⟩+≡
```

23.2.6 Unit Tests

⟨*Commands: public*⟩+≡
```
    public :: commands_test
```

⟨*Commands: tests*⟩≡
```
    subroutine commands_test (u, results)
      integer, intent(in) :: u
      type(test_results_t), intent(inout) :: results
```
⟨*Commands: execute tests*⟩
```
    end subroutine commands_test
```

Prepare Sindarin code

This routine parses an internal file, prints the parse tree, and returns a parse
node to the root. We use the routine in the tests below.

⟨*Commands: tests*⟩+≡
```
    subroutine parse_ifile (ifile, pn_root, u)
      type(ifile_t), intent(in) :: ifile
      type(parse_node_t), pointer, intent(out) :: pn_root
      integer, intent(in), optional :: u
      type(stream_t), target :: stream
      type(lexer_t), target :: lexer
      type(parse_tree_t) :: parse_tree

      call lexer_init_cmd_list (lexer)
      call stream_init (stream, ifile)
      call lexer_assign_stream (lexer, stream)

      call parse_tree_init (parse_tree, syntax_cmd_list, lexer)
      if (present (u))  call parse_tree_write (parse_tree, u)
      pn_root => parse_tree_get_root_ptr (parse_tree)
```

```
      call stream_final (stream)
      call lexer_final (lexer)
    end subroutine parse_ifile
```

Empty command list

Compile and execute an empty command list. Should do nothing but test the integrity of the workflow.

⟨*Commands: execute tests*⟩≡
```
    call test (commands_1, "commands_1", &
         "empty command list", &
         u, results)
```

⟨*Commands: tests*⟩+≡
```
    subroutine commands_1 (u)
      integer, intent(in) :: u
      type(ifile_t) :: ifile
      type(command_list_t), target :: command_list
      type(rt_data_t), target :: global
      type(parse_node_t), pointer :: pn_root

      write (u, "(A)")  "* Test output: commands_1"
      write (u, "(A)")  "*   Purpose: compile and execute empty command list"
      write (u, "(A)")

      write (u, "(A)")  "*  Initialization"
      write (u, "(A)")

      call syntax_cmd_list_init ()
      call global%global_init ()

      write (u, "(A)")  "*  Parse empty file"
      write (u, "(A)")

      call parse_ifile (ifile, pn_root, u)

      write (u, "(A)")
      write (u, "(A)")  "* Compile command list"

      if (associated (pn_root)) then
         call command_list%compile (pn_root, global)
      end if

      write (u, "(A)")
      write (u, "(A)")  "* Execute command list"

   write (u, "(A)")  "* Test output end: commands_3"

end subroutine commands_3
```

Compile Process

Read a model, then declare a process and compile the library. The process library is allocated explicitly. For the process definition, We take the default (`unit_test`) method. There is no external code, so compilation of the library is merely a formal status change.

⟨*Commands: execute tests*⟩+≡
```
    call test (commands_4, "commands_4", &
        "compilation", &
        u, results)
```

⟨*Commands: tests*⟩+≡
```
    subroutine commands_4 (u)
      integer, intent(in) :: u
      type(ifile_t) :: ifile
      type(command_list_t), target :: command_list
      type(rt_data_t), target :: global
      type(parse_node_t), pointer :: pn_root
      type(prclib_entry_t), pointer :: lib

      write (u, "(A)")  "* Test output: commands_4"
      write (u, "(A)")  "*   Purpose: define process and compile library"
      write (u, "(A)")

      write (u, "(A)")  "*  Initialization"
      write (u, "(A)")

      call syntax_cmd_list_init ()
      call syntax_model_file_init ()
      call global%global_init ()
      call var_list_set_string (global%var_list, var_str ("$method"), &
          var_str ("unit_test"), is_known=.true.)

      allocate (lib)
      call lib%init (var_str ("lib_cmd4"))
      call global%add_prclib (lib)

      write (u, "(A)")  "*  Input file"
      write (u, "(A)")

      call ifile_append (ifile, 'model = "Test"')
      call ifile_append (ifile, 'process t4 = s, s => s, s')
      call ifile_append (ifile, 'compile ("lib_cmd4")')

      call ifile_write (ifile, u)

      write (u, "(A)")
      write (u, "(A)")  "*  Parse file"
      write (u, "(A)")

      call parse_ifile (ifile, pn_root, u)

      write (u, "(A)")
      write (u, "(A)")  "* Compile command list"
      write (u, "(A)")
```

3137

```
      call command_list%compile (pn_root, global)
      call command_list%write (u)

⟨*Standard module head*⟩

⟨*WHIZARD: public*⟩

⟨*WHIZARD: types*⟩

```
    save

  contains

  ⟨WHIZARD: procedures⟩

  end module whizard
```

23.3.1 Options

Here we introduce a wrapper that holds various user options, so they can transparently be passed from the main program to the `whizard` object. Most parameters are used for initializing the `global` state.

⟨*WHIZARD: public*⟩≡
```
    public :: whizard_options_t
```

⟨*WHIZARD: types*⟩≡
```
    type :: whizard_options_t
      type(string_t) :: preload_model
      type(string_t) :: default_lib
      type(string_t) :: preload_libraries
      logical :: rebuild_library = .false.
      logical :: recompile_library = .false.
      logical :: rebuild_user
      logical :: rebuild_phs = .false.
      logical :: rebuild_grids = .false.
      logical :: rebuild_events = .false.
    end type whizard_options_t
```

23.3.2 Parse tree stack

We collect all parse trees that we generate in the `whizard` object. To this end, we create a stack of parse trees. They must not be finalized before the `global` object is finalized, because items such as a cut definition may contain references to the parse tree from which they were generated.

⟨*WHIZARD: types*⟩+≡
```
    type, extends (parse_tree_t) :: pt_entry_t
      type(pt_entry_t), pointer :: previous => null ()
    end type pt_entry_t
```

This is the stack. Since we always prepend, we just need the `last` pointer.

⟨*WHIZARD: types*⟩+≡
```
    type :: pt_stack_t
      type(pt_entry_t), pointer :: last => null ()
     contains
     ⟨WHIZARD: pt stack: TBP⟩
    end type pt_stack_t
```

The finalizer is called at the very end.

⟨*WHIZARD: pt stack: TBP*⟩≡
```
    procedure :: final => pt_stack_final
```

⟨*WHIZARD: procedures*⟩≡
```
    subroutine pt_stack_final (pt_stack)
      class(pt_stack_t), intent(inout) :: pt_stack
      type(pt_entry_t), pointer :: current
      do while (associated (pt_stack%last))
         current => pt_stack%last
         pt_stack%last => current%previous
         call parse_tree_final (current%parse_tree_t)
         deallocate (current)
      end do
    end subroutine pt_stack_final
```

Create and push a new entry, keeping the previous ones.
⟨*WHIZARD: pt stack: TBP*⟩+≡
```
    procedure :: push => pt_stack_push
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine pt_stack_push (pt_stack, parse_tree)
      class(pt_stack_t), intent(inout) :: pt_stack
      type(parse_tree_t), intent(out), pointer :: parse_tree
      type(pt_entry_t), pointer :: current
      allocate (current)
      parse_tree => current%parse_tree_t
      current%previous => pt_stack%last
      pt_stack%last => current
    end subroutine pt_stack_push
```

23.3.3 The `whizard` object

An object of type `whizard_t` is the top-level wrapper for a WHIZARD instance. The object holds various default settings and the current state of the generator, the `global` object of type `rt_data_t`. This object contains, for instance, the list of variables and the process libraries.

Since components of the `global` subobject are frequently used as targets, the `whizard` object should also consistently carry the `target` attribute.

The various self-tests do no not use this object. They initialize only specific subsets of the system, according to their needs.

Note: we intend to allow several concurrent instances. In the current implementation, there are still a few obstacles to this: the model library and the syntax tables are global variables, and the error handling uses global state. This should be improved.

⟨*WHIZARD: public*⟩+≡
```
    public :: whizard_t
```

⟨*WHIZARD: types*⟩+≡
```
    type :: whizard_t
      type(whizard_options_t) :: options
      type(rt_data_t) :: global
      type(pt_stack_t) :: pt_stack
     contains
     ⟨WHIZARD: whizard: TBP⟩
    end type whizard_t
```

3190

23.3.4 Initialization and finalization

⟨*WHIZARD: whizard: TBP*⟩≡
```
    procedure :: init => whizard_init
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine whizard_init (whizard, options, paths, logfile)
      class(whizard_t), intent(out), target :: whizard
      type(whizard_options_t), intent(in) :: options
      type(paths_t), intent(in), optional :: paths
      type(string_t), intent(in), optional :: logfile
      call init_syntax_tables ()
      whizard%options = options
      call whizard%global%global_init (paths, logfile)
      call whizard%init_rebuild_flags ()
      call whizard%preload_model ()
      call whizard%preload_library ()
    end subroutine whizard_init
```

Apart from the global data which have been initialized above, the process and model lists need to be finalized.

⟨*WHIZARD: whizard: TBP*⟩+≡
```
    procedure :: final => whizard_final
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine whizard_final (whizard)
      class(whizard_t), intent(inout), target :: whizard
      call whizard%global%final ()
      call whizard%pt_stack%final ()
  !!! JRR: WK please check (#529)
      !    call user_code_final ()
      call final_syntax_tables ()
    end subroutine whizard_final
```

Set the rebuild flags. They can be specified on the command line and set the initial value for the associated logical variables.

⟨*WHIZARD: whizard: TBP*⟩+≡
```
    procedure :: init_rebuild_flags => whizard_init_rebuild_flags
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine whizard_init_rebuild_flags (whizard)
      class(whizard_t), intent(inout), target :: whizard
      associate (var_list => whizard%global%var_list, options => whizard%options)
        call var_list_append_log &
            (var_list, var_str ("?rebuild_library"), options%rebuild_library, &
            intrinsic=.true.)
        call var_list_append_log &
            (var_list, var_str ("?recompile_library"), &
            options%recompile_library, &
            intrinsic=.true.)
        call var_list_append_log &
            (var_list, var_str ("?rebuild_phase_space"), options%rebuild_phs, &
```

```
            intrinsic=.true.)
        call var_list_append_log &
             (var_list, var_str ("?rebuild_grids"), options%rebuild_grids, &
             intrinsic=.true.)
        call var_list_append_log &
             (var_list, var_str ("?rebuild_events"), options%rebuild_events, &
             intrinsic=.true.)
      end associate
    end subroutine whizard_init_rebuild_flags
```

This procedure preloads a model, if a model name is given.

⟨*WHIZARD: whizard: TBP*⟩+≡
```
    procedure :: preload_model => whizard_preload_model
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine whizard_preload_model (whizard)
      class(whizard_t), intent(inout), target :: whizard
      type(string_t) :: model_name, filename
      model_name = whizard%options%preload_model
      if (model_name /= "") then
         filename = model_name // ".mdl"
         call whizard%global%read_model (model_name, filename)
         if (associated (whizard%global%model)) then
            call msg_message ("Preloaded model: " &
                 // char (model_name))
         else
            call msg_fatal ("Preloading model " // char (model_name) &
                 // " failed")
         end if
      else
         call msg_message ("No model preloaded")
      end if
    end subroutine whizard_preload_model
```

This procedure preloads a library, if a library name is given.

Note: This version just opens a new library with that name. It does not load (yet) an existing library on file, as previous WHIZARD versions would do.

⟨*WHIZARD: whizard: TBP*⟩+≡
```
    procedure :: preload_library => whizard_preload_library
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine whizard_preload_library (whizard)
      class(whizard_t), intent(inout), target :: whizard
      type(string_t) :: library_name, libs
      type(string_t), dimension(:), allocatable :: libname_static
      type(prclib_entry_t), pointer :: lib_entry
      integer :: i
      call get_prclib_static (libname_static)
      do i = 1, size (libname_static)
         allocate (lib_entry)
         call lib_entry%init_static (libname_static(i))
         call whizard%global%add_prclib (lib_entry)
      end do
      libs = adjustl (whizard%options%preload_libraries)
```

```
      if (libs == "" .and. whizard%options%default_lib /= "") then
            allocate (lib_entry)
            call lib_entry%init (whizard%options%default_lib)

```

23.3.5 Initialization and finalization (old version)

These procedures initialize and finalize global variables. Most of them are collected in the `global` data record located here, the others are syntax tables located in various modules, which do not change during program execution. Furthermore, there is a global model list and a global process store, which get filled during program execution but are finalized here.

During initialization, we can preload a default model and initialize a default library for setting up processes. The default library is loaded if requested by the setup. Further libraries can be loaded as specified by command-line flags. Initialize/finalize the syntax tables used by WHIZARD:

⟨*WHIZARD: public*⟩+≡
```
    public :: init_syntax_tables
    public :: final_syntax_tables
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine init_syntax_tables ()
      call syntax_model_file_init ()
      call syntax_phs_forest_init ()
      call syntax_pexpr_init ()
      call syntax_slha_init ()
      call syntax_blha_contract_init ()
      call syntax_cmd_list_init ()
    end subroutine init_syntax_tables

    subroutine final_syntax_tables ()
      call syntax_model_file_final ()
      call syntax_phs_forest_final ()
      call syntax_pexpr_final ()
      call syntax_slha_final ()
      call syntax_blha_contract_final ()
      call syntax_cmd_list_final ()
    end subroutine final_syntax_tables
```

Write the syntax tables to external files.

⟨*WHIZARD: public*⟩+≡
```
    public :: write_syntax_tables
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine write_syntax_tables ()

    end subroutine write_syntax_tables
```

23.3.6   Execute command lists

Process commands given on the command line, stored as an `ifile`. The whole input is read, compiled and executed as a whole.

⟨*WHIZARD: whizard: TBP*⟩+≡
```
    procedure :: process_ifile => whizard_process_ifile
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine whizard_process_ifile (whizard, ifile, quit, quit_code)
      class(whizard_t), intent(inout), target :: whizard
      type(ifile_t), intent(in) :: ifile
      logical, intent(out) :: quit
      integer, intent(out) :: quit_code
      type(lexer_t), target :: lexer
      type(stream_t), target :: stream
      call msg_message ("Reading commands given on the command line")
      call lexer_init_cmd_list (lexer)
      call stream_init (stream, ifile)
      call whizard%process_stream (stream, lexer, quit, quit_code)
      call stream_final (stream)
      call lexer_final (lexer)
    end subroutine whizard_process_ifile
```

Process standard input as a command list. The whole input is read, compiled
and executed as a whole.
⟨*WHIZARD: whizard: TBP*⟩+≡
```
    procedure :: process_stdin => whizard_process_stdin
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine whizard_process_stdin (whizard, quit, quit_code)
      class(whizard_t), intent(inout), target :: whizard
      logical, intent(out) :: quit
      integer, intent(out) :: quit_code
      type(lexer_t), target :: lexer
      type(stream_t), target :: stream
      call msg_message ("Reading commands from standard input")
      call lexer_init_cmd_list (lexer)
      call stream_init (stream, 5)
      call whizard%process_stream (stream, lexer, quit, quit_code)
      call stream_final (stream)
      call lexer_final (lexer)
    end subroutine whizard_process_stdin
```

Process a file as a command list.
⟨*WHIZARD: whizard: TBP*⟩+≡
```
    procedure :: process_file => whizard_process_file
```

⟨*WHIZARD: procedures*⟩+≡
```
    subroutine whizard_process_file (whizard, file, quit, quit_code)
      class(whizard_t), intent(inout), target :: whizard
      type(string_t), intent(in) :: file
      logical, intent(out) :: quit
